ON Monday a loan exhibition was opened in the Walsall Free Library. Mr. Whitworth Wallis, the curator of the Birmingham Art Gallery, delivered an address. He said it would have been more satisfactory if an artist occupied his place on the occasion. He could lay no claim to being an artist in the usually accepted sense of the term. If not an artist, however, he was in some degree a teacher, as the museum which he had the honour to direct was a school of archaeology and of art—a school where they were always endeavouring to bring the best influence of the art of the past to bear upon the art of to-day, so that the study of beauty and its introduction into material objects, the household chattels of the present time, from jewellery to enamelled ware, pots and pans, might be fostered by the students and artisans engaged in the numerous industries connected with the great Midland metropolis. There were no limits to the progress to be made in this direction, just as there were no boundaries to the reality of the earnestness which the working man—or, better still, the manufacturer—might bring to bear in beautifying the objects which it was their business to produce. He trusted no one would think him unmindful of the great kindness of Mr. Hill, the owner of the collection of pictures before them, for no one knew better than he did himself the great self-denial practised by owners of fine works when allowing their treasures to be removed from the dining-room or drawing-room walls for the benefit of the public, when he said—and he said it in no captious spirit—he was sorry that in the collection it had not been possible to gather together a few fine objects of industrial and decorative art from the immediate neighbourhood. He was, however, delighted that the Kensington loan was there, and the objects shown would teach the people of Walsall that art could be more than water-colours and oil paintings, bronze or marble statues, and that there was just as much art in a beautiful chalice from some old monastery, in the wood-carving of cathedral choir-stalls, or the painted saints upon its windows, and the thousand and one objects of everyday life if endowed with beauty of form and design, as in the numerous pictures which covered the walls of their galleries in London and the provinces. He hoped the collection might lead to the founding of such a museum, not of fossilised and barbarous curiosities, such as the bridle worn by a Derby winner, or the handcuffs worn by Palmer the murderer, which were offered to him, but objects which should have more than a passing interest for the student and workman—a museum to which men might bring their wives and families after their work was done (for it must be open in the evening), and by contemplation of the objects be lifted out of themselves. The study of such objects would bit by bit raise a more intelligent idea of what was good and what was bad in taste and in style, and the occasional half-hour spent in looking at such treasures should provide pleasure, not at the time, but after, for the reason that being things of beauty they should be joys for ever. In a rich locality like that there must be many ladies and gentlemen, who, without missing the money, could give a few thousands to form a small museum and art gallery. To this the municipality could contribute, and they would, he was sure, receive ample aid from the Science and Art Department; for he held it was the province of that department, and of every municipality, to provide something of art culture,

even in a small way, for those who could not avail themselves of the advantages which were offered by larger towns. Mr. Wallis then alluded to the good work done by the local school of art, and warned his hearers not to regard the study of art as a light or gentlemanly calling, by which they might easily stride up the ladder of fame as a member of the Royal Academy. All really great art demanded the devotion of a lifetime industry, together with earnestness, a vivid, lofty imagination, and a fine sense of noble colour—the latter a godlike gift vouchsafed to few. He asked all who had such a conception of the ease of art to pause before they entered upon the fierce struggle for life and fame among the already overcrowded ranks of picture-painters, and see if they could not turn their attention to design for manufacturers, to the interior decoration of houses and public buildings, and to illustrations of books, similar to the good work done in this respect by the Birmingham school. Three fields of art to be explored and conquered were here opened to them, and it was infinitely to be preferred that they should assist in the production of beautiful and delightful specimens of industrial and decorative art than that they should eke out a precarious existence by the painting of meretricious and effete pot-boilers. Having enlarged upon these points and impressed upon his hearers that the highest art was closely and generally allied to extreme simplicity, and that the possession of ample means was helpless in the domain of art without cultured taste and refinement, Mr. Wallis said the best and greatest art, the gentle-hearted adoration of the fifteenth and sixteenth century Italian, the stern and vigorous realism of the Dutchman, the mystic ideals of the Flemings, the golden glories of the Frenchman Claude, the ineffable beauties of Ramsey, Gainsborough and Reynolds, the brilliant colourings of Turner; the fresh, breezy landscapes of Constable, Crome, De Wint, and dear old David Cox; and last, but not least, the triumphs of that most remarkable development of art, or art movement, of modern times, the works of the English pre-Raphaelites, Mr. Holman Hunt, Millais and Ford Madox Brown—those, and the works of kindred spirits, would endure. The study of art, he said in conclusion, was a life study; it was never finished, and never could be finished; therefore, he did not think it should be looked upon as a fascinating and a profitable way of spending one's time, but rather as a pursuit which should lift one out of the materialities of time, and carry one forward to higher refinement and higher progress.

BRADFORD SOCIETY OF ARCHITECTS AND SURVEYORS.

THE members of this society had their summer excursion on Friday last to the ancient city of York. Among those present were Mr. Wheeler Smith (president), Messrs. H. Perkins and A. B. Burleigh (president and secretary of the York Architectural Society), Messrs. T. H. Healey, Charles Gott, C. H. Hargreaves, W. B. Woodhead, B. D. Fairbank (hon. secretary), John Hindle, R. Armistead, T. C. Hope, B. Cowgill, James Young, H. Marten, J. Flew, Thomas Barker, C. E. Milnes, C. H. Gott and A. G. Adkin. Ladies again joined the excursion. Luncheon was served at the Royal Station Hotel on arrival, and afterwards the party went to view the Minster, St. Mary's Abbey, and other interesting buildings. After dinner "The Health of the Guests" was proposed by the President, and responded to by Messrs. Perkins and Burleigh. The toast of "The Ladies" was submitted by Mr. C. H. Gott, and responded to by Messrs. Armistead and Healey. A photograph of the group was taken by Mr. Burleigh in the hotel gardens, and the party returned home after a very pleasant trip.

Some Architect's, Surveyor's and Valuer's Text-books.

SIR,—Serious mistakes are frequently made by members of our profession, owing to not having a text-book clearly showing the orthodox way of preparing valuations, and the great difference in amounts between their valuations tends to bring it into disrepute.

Although nearly all architectural surveyor's text-books state that ground rents are worth from 25 to 30 years' purchase, still, where examples of valuations are supplied, the ground rent is deducted as an annual leakage, instead of it being capitalised separately, thereby giving a fictitious sum as the value. Professor Banister Fletcher, who is the author of several very valuable professional works, unfortunately does this in his "Valuations and Compensations," 1893, pp. 87-88. "Suppose your client holds upon lease for twenty-three years

unexpired, at 50% a year, a property let on weekly tenancies, and producing a gross rental of

Per annum	£500 0 0
From this we must deduct ground rent .	£50 0 0
Rates and taxes, losses by empties, &c., annual repairs, insurances, &c., 33 per cent., or one-third .	166 0 0
	216 0 0
	284 0 0

This income for 23 years, to pay 6 per cent., is worth 12'30 years' purchase, or	3,493 4 0
Now suppose the value of the dilapidations be	300 0 0
The remainder	3,193 4 0

will represent the value of the property."

The learned gentleman also falls into the error of using the wrong tables, which give the same rate of interest for the sinking fund as the interest required on the capital, and this is an impossibility (see pp. 121-23). He should have used those contained in Hurst's "Architectural Surveyor's Handbook," 1891, pp. 416-18, which give 3 per cent. compound interest for the sinking fund to replace the capital and 6 per cent. on the capital. The correct working out of the example aforesaid would be thus:—

Gross annual rental	£500 0 0
Less annual leakages	166 0 0
	334 0 0
23 years in the 6 per cent. table gives years' purchase	11'0115
	3,677 16 9
Less capitalised value of ground rent	£50 0 0
Secured for 23 years in the 3½ per cent. table gives years' purchase .	15'1943 = 759 14 3
	2,918 2 6
Less dilapidations	300 0 0
Correct value	2,618 2 6

Or a difference of 575*l.* 1*s.* 6*d.*, which a purchaser is asked to pay in excess of the value. In another example, at pp. 24-26, the gentleman makes the same mistake, and at p. 84, through using the 4 per cent. table for the rack rent and the 5 per cent. for the ground rent (besides giving the wrong multiples), a mistake is made amounting to 2,826*l.* 2*s.* Notwithstanding the article on the "Valuations of Buildings" in Hurst's excellent work aforesaid, pp. 380-381, is most exhaustive, still the following paragraph is most misleading, as a valuer might be induced to fall into the same error as the professor and others have done: "When the ground is held on lease, its rent becomes a deduction from the gross rental received by the owner of the buildings," whereas at p. 383 the reader is informed that ground rents six times covered should yield interest from 3½ to 4 per cent.

Another mistake made by surveyors is that of using the same table for the freehold interest as that of the leasehold. This should not be done owing to the risks of forfeiture on a breach of any of the covenants usually contained in short leases. It is to be regretted that the Earl of Derby's surveyor recently did so, in addition to wrongly treating the ground rent as an annual leakage. See a pamphlet on "The Derby Estates," 1894, by "W. B." Lord Derby and other large land-owners are now graciously willing to change the customary 75 or 99 years' leases for long leases of 999 years, or practically freeholds (as the value of the reversion beyond this time would be *nil*), on payment of a fine commensurate with the benefit derived, or will in the alternative commute the fine into an annual ground rent in addition to the one already existing. The Liverpool Corporation sell the reversions of their properties and commute the purchase money into perpetual ground rents; and an absurd theory has sprung up which is calculated to do an immense amount of injury to owners of real estate, viz. that the difference in value between a 75 years' lease and a freehold is about 5 per cent.; *vide* "The Liverpool Corporation Leaseholders' Committee's Report," 1887, pp. 71-84, and a letter written to Lord Derby by Mr. W. Evans, President of the North Liverpool, Bootle, Walton and West Derby Property Owners' Association. See the *Liverpool Mercury*, February 11, 1895. This arises from using the wrong tables. On referring to Inwood's (common) "Tables for Valuing Estates," 1870, p. 8, in the 5 per cent. column it will be found that the multiples of a 75 years' lease are 19'485, or about 19½ years' purchase, whereas in perpetuity they are 20'000, or about half a year's

purchase difference; but, as previously pointed out, this is not the correct table to use, as it is assumed that the same rate of interest can be obtained for the sinking fund to replace the capital invested as that at which the property is purchased, which amounts to an absurdity. Hurst's said work, pp. 384-418, should be consulted, where 5 per cent. interest is given on the purchase money, and the sinking fund is worked out at 3 per cent. compound interest, and the multiples respectively of a 75 years' lease and a freehold are 18'633 and 20'000, or about 1½ year's purchase difference; and still further, as the same table should not be used for a freehold interest as for a leasehold one for a short time—as previously referred to, the 5 per cent. should be used for the freehold and the 6 per cent. for the leasehold—the multiples would be 20'000 and 15'706, or nearly 4½ years' purchase difference; if the 6 per cent. is used for the former class and the 7 per cent. for the latter, the multiples would be 16'667 or about 16½ years' purchase, and 13'574 or 3'093 years' purchase difference; or about 18½ per cent. and not 5 per cent. In Gwilt's "Encyclopædia of Architecture," 1881, which is considered to be a work of erudition, an example is given at p. 1079 in which the rent paid by the lessee is less than the actual value of the premises; the 5 per cent. table is used, whereas it occurs to me the 6 per cent. one would be the correct one to use. This would give 10'540 years' purchase, and not the wrong multiples of 12'8211. The whole of the tables at pp. 1102-5 are inapplicable for valuing estates, and are almost similar to those of Professor Fletcher. Another example at p. 1080 is misleading; the annual leakages are excessive, and a bracketed note states, "In a leasehold valuation the ground rent would also have to be deducted," so that the valuer following this advice would make the same mistake in a similar way to the professor; the wrong multiples are also used. Tarbuck, in his "Handbook of House Property," 1875, pp. 177, 178 and 179, deducts the ground and quit rent wrongly as an annual leakage, and at 70'190 he supplies an example of copyhold tenure, and states that "freehold value, less cost of enfranchisement, may be thus calculated":—

Net income of	£100	
Multipled by years' purchase	25 =	£2,500

For the fee simple.	
And capitalising the net rent	£100
At the age of seventy at years' purchase	5 = £500

Adding for a clear quit rent of 10s. per annum, twenty-eight years' purchase	14
For a heriot, best beast	10
One-fifth the yearly land rental or minerals	10
And one-fourth value of timber, or	16
	<u>550</u>
	£1,950

Steward's fees, with other expenses, have not been taken into account.

In general practice is it not better to use the 5 per cent. table, instead of the 4 per cent. one, for the freehold (which is usually adopted for ground rents)? The example would then work out thus:—

<i>Freehold Interest.</i>		
Net income of	£100	
In the 5 per cent. table gives years' purchase	20 =	£2,000 0 0

<i>Cost of Enfranchisement.</i>		
Net rental	£100	
At the age of seventy, years' purchase	5 = £500	
Heriot	10	
Minerals	10	
Timber	16	
	<u>536 0 0</u>	
	£1,464 0 0	

Yearly quit rent	£0 10 0
In perpetuity 3½ per cent. table, years' purchase	28'571
	<u>14 5 8</u>
	£1,449 14 4

Exclusive of steward's fees, 11% 10s., and valuer's and solicitor's fees.

In this case the way the quit rent is treated is immaterial, as it is not deducted as an annual leakage, leaving the remainder to be capitalised like the examples given at pp. 177, 178 and 179, but still I think the form adopted by me appears to be more correct in keeping the quit rent distinct from the other deductions. An able paper on the subject of "The Enfranchisement of Copyholds of Inheritance" was read at a meeting of the Institution of Surveyors, January 10, 1870, by Mr. W. Smyth, and was duly recorded in the columns of the *Building News*. The new Copyhold Act, 1894, has come into operation; it annuls a part of the previous acts. The publication of the "Calendars of State Papers" and the "Records of the Manorial Courts Baron" within the last two decades has thrown new light on the question. The minutes of the Board of Agriculture, annuity tables and scale of compensations, to be obtained from the secretary, should be consulted by the student of this branch of the profession. It is my sincere wish that the gentleman whose works have been referred to will take it in good part within the interests of the profession; and that the subject matter will form the basis of a standard work which I hope to issue ere long—Yours,

JOSEPH HENRY MCGOVERN,
Fellow of the Liverpool Architectural Society.
8 Vernon Street, Liverpool:
June 20, 1895.

GENERAL.

The Restoration of Metz Cathedral, which was suspended twenty-five years ago through the Franco-German War, is to be resumed. A lottery to raise funds has been sanctioned by the Government.

Marble weighing 72,999 tons was sent by sea from Carrara and Massa during 1894. Out of that quantity 19,293 tons were imported to Great Britain, and 28,669 tons to America.

Sir Whittaker Ellis has been elected chairman of the Privileges Committee of the Corporation of London in succession to Sir William Lawrence, who lately retired.

Mr. H. S. Marks, R.A., has removed from Hamilton Terrace to 5 St. Edmund's Terrace, Regent's Park, N.W.

Mr. Lerner Sugden, of Leek, has been elected surveyor to the Stoke Rural District Council and engineer to the Bucknall sewage scheme.

Mr. James Blyth has offered 300*l.* to the British Dairy Farmers' Association, in order that three prizes of 100*l.* each may be offered at their forthcoming show at Islington for drawings and plans for dairies, also for the best limited size model permanent dairies and for the best portable dairies.

A Meeting of the Iron and Steel Institute will be held in Birmingham on August 20, 21, and 22.

The Bill for the rebuilding of Vauxhall Bridge has passed the Lords Committee.

The Helensburgh Naturalist and Antiquarian Society on Saturday visited the rock sculpturings at Auchentorlie, Bowling, which were recently discovered by one of the members.

The Arts and Crafts Exhibition in Manchester, which closed on Saturday, was visited by 527,577 people during the eleven weeks it was open.

Baron Edmond Rothschild has bought and presented to the Louvre the Bosco-Reale treasure, consisting of forty silver articles, which were tied up and concealed in a niche at the time of the destruction of Pompeii in the year 79. The Louvre had declined to give the 500,000 frs. demanded for the collection.

The Siddons Memorial on Paddington Green is to be an adaptation of Reynolds's portrait of the actress as *The Tragic Muse*.

Sir F. Leighton, P.R.A., was present at the marriage of the Duc d'Aosta and the Princess Hélène of Orleans at Surbiton on Tuesday.

The Seascope by J. S. Cotman, which excited extraordinary attention when exhibited at Burlington House, has been ceded by Messrs. Agnew, who bought it at the sale of the Price collection, to the trustees of the National Gallery.

A Company has been formed for the purpose of creating a summer and winter resort, under the title of Mayville, on the French coast, in the neighbourhood of Etaples. Calais and Boulogne are no longer attractive; there is consequently an opening for the new Mayville, which will have all the advantages that experience has shown to be necessary. It is sufficient to say that M. Charles Garnier, of Paris, and Mr. A. Darbyshire, of Manchester, will be responsible for the architecture, in order to make it clear that grace, beauty, comfort, and sanitation will be the characteristics of the dwellings. The company is as much deserving of support in England as in France, and it is likely to be most prosperous for the shareholders.

NEW READING CASE.

To Librarians of the Public Libraries and Reading-rooms.—A new handsome Reading Case can be supplied at a nominal charge of 2s., by post 2s. 6d., on early application to the Publisher, 175 Strand, W.C.

SPECIAL NOTICE TO THE TRADE AND OTHERS

[Extract from a lecture on Architects' Libraries by Professor T. Roger Smith, F.R.I.B.A., at University College, October 10, 1893.]

"Lastly, let me recommend the back volumes of the professional journals. In the course of years all sorts of architectural topics come up in the public press and before the professional societies, and if you hunt through the indexes of these publications when you are seeking for information which eludes you in books, you will often be rewarded."

There has been a considerable demand for the back numbers of *The Architect* during the last three or four months, which we have no doubt has arisen from the remarks made by Professor Roger Smith, as contained in the above quotation; but the consequence has been that our stock of back numbers is getting very low, and consequently, in future, the charge for back numbers of previous date to January 12, 1894, will be 6d. each.

A few of the back volumes may still be had, price 12s. each.

EDITORIAL NOTICES.

The authors of signed articles and papers read in public must necessarily be held responsible for their contents.

No communication can be inserted unless authenticated by the name and address of the writer—not in every case for publication, but as a guarantee of good faith.

Correspondents are requested as much as possible to make their communications brief. The space we can devote to Correspondence will not usually permit our inserting lengthy communications.

WINSOR & NEWTON'S

"Waterproof"

INDIAN INK.

This new preparation—made from genuine Indian Ink—has been introduced to meet the requirements of those Artists, Architects and Designers who wish to lay washes of colour over drawings in ink.

Unlike many so-called Indelible Inks, "Waterproof Indian Ink," when dry, will be found absolutely unaffected by subsequent wetting.

A PORTRAIT WINDOW.

AN interesting window has been placed in the section of the National Portrait Gallery of Scotland devoted to the Museum of the Societies of Antiquaries of Scotland. It is the gift of Mr. J. R. Findlay to the Board of Manufactures, and commemorates the opening of the museum in the new building on August 13, 1891, on the occasion of the meeting in Scotland of the Royal Archæological Institute. The window, designed by Dr. Rowand Anderson, the Board's architect, and executed by Mr. W. G. Boss, contains portraits of the office-bearers of the Society at the date in question. Its position is at the top of the east staircase, and is readily seen from the landing which gives access to the council-room of the Antiquarian Society. It is divided into two lights, and the portrait medallions are arranged in sets of two on each side of the stone mullion. That of Her Majesty the Queen, the patroness of the Society, is inserted where, in ordinary circumstances, the tracery would

be, between the points of the two arches. Below the arching of each light is a medallion—that on the left carrying the Royal Arms, while the right has the arms of the Society of Antiquaries of Scotland. The portraits come next in the following order:—On the left side, the Marquis of Lothian, K.T., LL.D. (president), and J. R. Findlay (vice-president); Sir Noel Paton, LL.D., R.S.A., and Sir W. Fettes Douglas (councillors); R. Rowand Anderson, LL.D., architect, and T. Dawson Brodie, W.S. (councillors), James Macdonald, LL.D. (councillor), and Dr. David Christison (secretary), Thomas Dickson, LL.D., and Sir Arthur Mitchell, K.C.B. (secretaries for foreign correspondence); Gilbert Goudie (treasurer), and Adam B. Richardson (curator of coins.) The portraits in the right-hand light, from the top downwards, are the Marquis of Bute and Sir Herbert Eustace Maxwell, Bart. (vice-presidents), Professor Sir William Turner, LL.D., and R. W. Cochrane Patrick, LL.D. (councillors), Aeneas J. G. Mackay, LL.D., and Reginald M'Leod (councillors); Dr. Robert Munro (secretary), and Joseph Anderson, LL.D. (assistant secretary); Robert Carfrae and Professor Duns, D.D. (curators), and John Taylor Brown (librarian). Balancing the medallion of Mr. Brown is one containing a female head with ears of wheat, symbolical of the period of the year when the museum was thrown open for the use of the public. It was on August 13, 1891, the date inscribed on the medallion, that this interesting ceremony took place. The portraits were done partly from photographs and partly from sittings given to Mr. Boss, and are all remarkably good likenesses of the noblemen and gentlemen represented. The heads are in glass of a silvery tint, set off by glass of a pretty shade of blue. Each head is enclosed in a circular floral wreath, with leaves and flowers of red berries; each wreath has a distinct design, and the whole of the coloured glass has a desirable purity and transparency of tint. The body of the window is of ordinary cathedral glass. The work involved in the preparation and mounting so many portraits was great, and had to be gone about with much care. In proof of this it may be noticed that in the medallion of the Queen alone there are over 200 pieces. The window forms an interesting memorial of an important event in the history of this national Society.

TENDERS are invited for an installation of electric light at the Guildhall, Bristol, by the City Electrical Engineer, Mr. Faraday Proctor, Temple Bank, Bristol.

VARIETIES.

At the meeting of the markets committee of the Leeds City Council it was decided, in view of the damage done by the late gale to the roof of the Kirkgate Market, to ask Mr. Hewson, the city engineer, to thoroughly examine the roof and report.

At the meeting of the Tendring School Board last week, Mr. J. W. Start, F.S.I., architect, of Colchester and Clacton-on-Sea, submitted plans for additions to the present school for ninety children, together with new offices, playgrounds, &c.

THE private Bills deposited this year amount to 170, of which number 138 relate to English undertakings, 16 to Scottish and 16 to Irish. Last year the number was 166.

INSTRUCTIONS have been given by the Cement Section of the London Chamber of Commerce to certain experts, who are not themselves cement manufacturers, to make exhaustive inquiries into the extent to which the introduction of Kentish rag and other materials into the manufacture of Portland cement may be found to prevail, and as to their effect on the quality of that article. These gentlemen have already commenced their investigations, the results of which they will report in due course as a basis for further action.

At the meeting of the Exeter City Council it was decided to apply for powers to borrow 42,000*l.* for sewage disposal purposes.

IN the dispute between Falkirk Town Council and Falkirk Joint-Stock Gas Company, Mr. Woodall, C.E., and Mr. Stevenson, C.E., London, the arbiters, have issued their award, giving the price to be paid by the Town Council for the undertaking of the Gas Company. Witnesses on behalf of the Gas

Company estimated the cost of the undertaking as high as 115,000*l.*, while witnesses for the Corporation estimated it as low as 33,000*l.* The arbiters fix the price at 77,050*l.*, to which sum falls to be added the expenses of the arbitration, the arbiters having decided that these should be borne by the Corporation.

The surveyor to the Malton Local Board, Mr. Richardson, has reported to that body in favour of an additional reservoir, and an additional well near the present reservoir, as a source of water supply for Malton. He also stated that the means recently taken to keep the water pure, by preventing contamination with flood water from the river Derwent, were calculated to be available for a flood up to 12 feet above the summer level.

The first cast has taken place at the recently erected Saltoun Iron Works, Falkirk, in presence of a large and representative gathering. These works, which belong to Mr. J. E. Gibson, late of Camelon Iron Company (Limited), are situated in Grahamston, in close proximity to Grahamston railway station, and the site is regarded as one of the best for an enterprise of the kind in the immediate neighbourhood of Falkirk. The works will afford employment for a large number of hands. Though at present only about two acres of ground are being utilised, nearly half of which is occupied by the buildings alone, more than double that space has been acquired for future extension.

The *Birmingham Post* says:—The total number of alarms of fires which the Birmingham fire brigade has attended during the past year has been 500, a decrease of 142 on the previous year. Of these 88 related to chimneys on fire, and 67 were false alarms. Of the 105 fires 7 were beyond the city boundary. The total loss is roughly estimated at 40,000*l.*, and the amount of property at risk at 1,700,000*l.* The most serious fire occurred on the premises of Messrs. Binley & Co., Smethwick, beyond the city boundary, and the next serious on the premises of Messrs. Heaven, Edgbaston Street.

The building of a new church of St. Paul at Auckland, New Zealand, is proposed, and an appeal for funds has been issued in this country.

The Great Western Railway Company, by a Bill deposited for consideration during the coming session, proposes to carry out a light railway by the conversion of the Lambourn Valley Railway, for which powers were granted in 1888, and which has not been constructed, into a tramroad. The line is to be subject to such conditions and restrictions as the Board

of Trade may impose; and for this and other works which are proposed in the Bill the company wishes to raise 300,000*l.* additional share capital, and to increase its borrowing powers by 100,000*l.*

At the Annual New Year Eisteddfod meeting at Dolgelly, Merioneth, Mr. Thomas Ellis, M.P., in his address said he desired to call attention to the crying need of attaining excellence in architecture. In many respects instrumental music and architecture were widely divergent in their method and appeal, but both arts were very similar in that they required patience, long training, devotion, an accumulated tradition of excellence, and those indefinable but priceless and indispensable gifts of touch and taste. In a word those two arts demanded, for their perfect development, genius. He hoped that Aberystwyth College would soon re-establish a department of music. Where to look for the training of men who could teach the erection of buildings which in their design bore the impress of the exercise of fine thought and high talent he did not know. But this he knew, that no country more sorely and urgently needed such teachers than Wales. All over Wales intermediate and technical schools were about to be built. Were they to be haphazard, ill-arranged, characterless and uninviting? Had Wales the architects and the popular taste and training which would model town and village, halls, institutes and libraries on something better than a gaol, a workhouse, or a barn? Year by year increasing numbers sought rest, leisure, recreation, natural beauty in the glens and along the seashores of Wales. But did the growing towns show traces of a characteristic and worthy Domestic architecture? Was there any serious endeavour to adapt farmhouses and cottages to character, to scenery, to climate, or to give to those buildings whose parts were determined by necessity such forms and colour as shall delight the mind? He ventured to think that that educational institution which seriously set itself to provide the Welsh people with guidance, knowledge and skill in the art of building well would receive the highest meed of praise and renown for distinguished service to the nation and dominion of Wales.

At Bangor an inquiry has been held by the Local Government Board in regard of an application for borrowing powers to carry out street improvements and sewerage works.

NEW Corporation stables, erected by Mr. James Wallace, builder, at a cost of about 3,000*l.*, have just been opened at Kilmarnock.

TRADE NOTES.

WE understand that great progress is being made with the Building Trades Exhibition, which opens at the Agricultural Hall in March next. Already the principal positions on the ground floor have been allotted, and several exhibitors have taken space in the galleries. The business character of the exhibition will be rigidly maintained, and there is every indication that the present year will see one of the best exhibitions of its kind.

WE have much pleasure in announcing that the Self-Lock Tile Company, of 49 Victoria Street, S.W., have just booked a large order for their patent tiles, nearly 3,000 feet, for the new premises of the Cork Pavement Company at Barking. They also inform us that they have a great number of orders to execute, and in consequence have been compelled to order a large number of extra machines.

A LARGE clock has just been erected in the tower of Brill parish church, Buckinghamshire, which strikes the hours, chimes the Cambridge quarters, and shows time on one dial facing south. It is fitted up with all the latest improvements, and made generally to the designs of Lord Grimthorpe, by Messrs. John Smith & Sons, Midland Clock Works, Derby. Mr. T. H. Seargeant, of London, was the donor.

THE new Board schools, Carlisle, for the Carlisle Board, are being warmed and ventilated throughout by means of Shorland's patent Manchester grates and patent ornamental exhaust roof ventilators, the same being supplied by Messrs. E. H. Shorland & Brother, of Manchester.

THE form of gully supplied by the Patent Gully Company, Limited, of Nottingham, is designed to remove certain disadvantages under older systems, and to save the money of the ratepayers. The gully is made from cast-iron. It is formed with a partition across to a determined height so as to form two chambers—one, the gully proper, and another of much less capacity to form a second. The outlet is from the second chamber by means of a dip pipe or tube of sufficient depth to form a trap. The flood water is carried away through the dip pipe to the drain, and this chamber is so constructed that the smallest amount of water therein forms an efficient seal. The second chamber being effectually protected, prevents any street

refuse getting in and evaporation taking place. The plug hole on the bend of the dip tube gives easy access to the drain without disturbing the streets. No corners are left in the gully proper, the bottom of the tank being so rounded that it can be thoroughly cleaned out with the ordinary scoop. The bell or bonnet attached to the grating is so formed that the surface of liquid in the tank exposed to the air is of the smallest possible description, being little more than the area of the outlet. The house gully is made in cast-iron or earthenware alone, or earthenware gully with cast-iron frame and grate.

WE notice reduction in prices by Mason & Co. (late F. Dyer) for the excellent patent automatic tidal valve trap and Dyer's air-tight manhole covers. These air-tight manhole covers have this advantage over others in the market. In addition to their great strength and neatness they are air-tight by pressure on india-rubber seating, as shown in section above. The cover entirely lifts out of the frame, with proper handles made for that purpose; thus the trouble of opening as in the hinged ones, through dirt setting same tight, and the danger of the cover (not then being easy to get beyond the perpendicular through rust, &c., in hinge) falling on any workman's head or hands engaged under them, is entirely removed.

PENDANTS and brackets are required in connection with the gas-fittings to be furnished for the new infirmary block of the Fife and Kinross District Lunatic Asylum at Springfield, Cupar. Messrs. Kinnear & Peddie, 3 South Charlotte Street, Edinburgh, are the architects.

WE would direct the attention of our readers to "Porcelaine" (Mr. T. R. I. Maurice, Lambeth, sole inventor and manufacturer). Any colour or tint is available, to judge from the samples to hand, and in addition to superseding enamels and paints it has the advantages of being non-poisonous, of quickly drying, and, after being applied, neither cracking, chipping, blistering or peeling off.

THE proposed Vauxhall Bridge, which is the object of a private Bill, is to have five arches, and to cost 484,000*l.* The works will occupy seven years. During the construction a temporary bridge will be erected near the British Gallery.

LONDON. W.

CARVED OAK AND ANTIQUE DEPARTMENT, No. 204 TOTTENHAM COURT ROAD,

ELECTRICAL.

THE Glasgow Corporation have asked Professor Becker, of Glasgow Observatory, to report regarding a system of regulating the public clocks by electricity.

AT the meeting of the Worcester City Council the electricity committee brought forward three candidates for the appointment of electrical engineer. The Council decided to refer the matter back to the committee, there being an opinion that the duties were to be undertaken by the city surveyor, and on that understanding his salary was fixed.

THE foundation-stone of the central station of the Islington Vestry for supplying electricity for lighting purposes under a provisional order obtained in 1893 has been laid at Eden Grove, Holloway. The site adjoins the Great Northern Railway, and the land was purchased from the railway company at a cost of about 9,000*l*. The central station, which will be built by Messrs. Macfarlane Brothers, from the designs of Mr. A. Hessel Tiltman, is to cost 18,000*l*., and the machinery and plant, including the mains and conduits and public lamps in the compulsory area, will cost 33,000*l*. more. The system adopted is that of a high tension alternating current, with transformers on the premises of the consumers; and for street arc lighting the same, with commutator transformers at the works, of the Ferranti type. Mr. Albert Gay, the electrical engineer of the Vestry, is superintending the carrying out of the work.

BUILDING AND BUILDERS.

THE Edinburgh Dean of Guild Court have granted eight warrants, and among them sanction to the North British Railway Company to erect a new parcel office at the Waverley Bridge in place of the present one and of much the same appearance, though larger.

THE *Glasgow Herald* says that at Hamilton the past year has been an exceptionally busy one in the building trade. The Dean of Guild Court have issued forty-seven linings against thirty-three in the previous year; while the estimated cost of the structures is 48,000*l*. against 27,000*l*.

THE *Manchester Guardian* says:—The bleaching and dyeing works of Messrs. Nathan Ramsden & Co., of Breightmet, near Bolton, have been destroyed by fire, the damage being estimated at 3,000*l*. The Bolton Corporation fire brigade were summoned, but as the buildings were outside their radius they (act-

ing on instructions) refused to attend. Before the Bury brigade arrived the works were doomed. A member of the firm declares that had the Bolton firemen attended when summoned the premises would not have been wrecked.

THE annual dinner to the Hereford Corporation workmen took place on Tuesday, the 1st inst., Mr. W. J. Humfrys, the mayor, presiding.

AT North Walsham a dinner was given in the Town Hall to the employes of Mr. William Wilson, builder, and Mr. William Coe, plumber and glazier, both of North Walsham. The idea of the dinner originated through Miss Moore and Mr. and Mrs. Harry Smith, of Sheringham, with whom Mr. Wilson and Mr. Coe have had extensive building contracts, who wished to show their appreciation of the manner in which the workmen had performed their duties by giving them a dinner.

AT Ipswich Mr. Henry Underwood has just given the annual dinner to his employes. The workmen engaged in building the new workshops were invited to attend, with the permanent staff, and the number present exceeded forty. Mr. Underwood presided. Mr. S. Foulger proposed "Success to the New Venture," referring to the perfect harmony existing between capital and labour in the firm; where such good feeling was shown any extension or new departure deserved success. Mr. Underwood, in response, said it was a source of satisfaction to him to see at these annual gatherings so many old faces. If he found that those employed were constantly leaving him he should soon look round for the cause. He hoped they would work together in the future as they had done in the past.

AT Newcastle-on-Tyne Mr. W. C. Tyrie, contractor, Newcastle and Gateshead, chairman of the Master Builders' Association, gave the annual dinner to his officials in the Collingwood Hotel. There was a large company, including a number of invited guests, and the host, in responding to the toast of his health and success to the firm, proposed by Mr. J. Tweddell, said he did not believe in the terms "employer and workmen;" they were all "fellow-workers," and he found them equally anxious with himself in all that made for the success of their business. Mr. Hall and Mr. Wilson responded for the officials, and remarked upon the consideration they at all times received from the head of the firm.

A MEETING of firms engaged in the building trade has been held at 31 Bedford Street, W.C., under the auspices of the Central Association of Master Builders. There was a large and representative attendance. In the course of the discussion which took place it was pointed out that many strikes have

ADVANTAGES.—By the use of this Patent Fanlight Opener, a Sash can be opened to any required distance, and the action of loosening the cord causes the cam to clip chain and hold securely.

The Chains, made in Copper, are impervious to all atmospheric influences, and being quite flexible the Opener works with the greatest ease. It is suitable for any size sash.

Working Models of the above and other Specialties may be seen at our new Showrooms, 57 HOLBORN VIADUCT, E.C. Architects and Builders are invited to inspect same.

The Patentees have every confidence in calling the attention of Architects, Builders, Ironmongers and the trade generally to their new Patent Window Openers, as possessing advantages over all other Fanlight Openers in the market.

occurred throughout the building trade of London since the last agreement between masters and men in 1892 ; that these strikes are almost of daily occurrence now, and that the almost sole reason for this is caused by the union men refusing to work with non-union men. It is therefore now resolved that a notice in the following terms should be posted on all works and jobs :—
 “ It is a condition of employment at these works that, in accordance with the understanding of 1892, no workman should be placed under any disability by reason of either belonging or not belonging to a trade society.”

AMERICAN NOTES.

THE *Scientific American* says :—A remarkable instance of the rapid formation of alluvial deposits from overloaded streams has been discovered by the Government geological expedition on the Yaktse River, in Alaska. This river in its course from the Chaix Hills to the sea passes through a tunnel in the Malaspina glacier, some 6 or 8 miles in length. When it finally emerges into the open air it is a very swiftly flowing stream of dark muddy water, 100 feet wide and about 20 feet in depth. Near the point where the river emerges from the ice it flows through a forest of large trees, and the gravel and sand carried along by the stream are deposited here to the depth of many feet. Some of the tallest trees still project through the deposit and retain their branches. The greater part, however, have been broken off and completely covered up by the sand. In other places the presence of vast forests is indicated by a few dead branches projecting through the deposits. In places where the deposits are thickest all signs of the trees have disappeared, and in their place nothing may be seen but broad sand flats. These are inundated in stormy weather, and are of about the consistency of quicksand.

THE same Journal adds :—The great dry dock at Port Orchard, Washington, now in course of construction, will be the second largest dry dock in the world. It is to be equipped with a timber and concrete dock 675 feet long, with a floor width of 67 feet. Its greatest width will be 130 feet and its depth 40 feet. The dock will be closed by a gate or caisson built in the form of a ship with a hull and a bow at either end. This will be constructed of iron. The gate is pierced by twelve 20-inch filling culverts, each fitted with a gate valve. For emptying the dock, three powerful centrifugal pumps are provided, each of which is operated by a

separate engine. The steam for operating the pumps will be supplied by six large steel tubular boilers. The boiler pressure will be 100 lbs. to the square inch, and the pumps will be capable of discharging 110,000 gallons of water per minute. The gate is, however, the most interesting feature of the dock. The upper part is supplied with a water compartment provided with two 20-inch sluices, one of which opens into the sea and one into the dry dock. The gate is closed by filling this compartment with water and sinking it, the water being admitted through two 20-inch valves. The gate is handled by the aid of a capstan worked by a vertical shaft from the engine on the lower deck.

THE *Engineering Record*, New York, says :—Water filtration in St. Louis, Mo., has been studied for several years by Water Commissioner M. L. Holman, C.E., who is convinced that the purification which the river water secures by subsidence in the large settling basins of the new works is not likely to be satisfactory for many years. The problem is a serious one, for the amount of water used in the city annually is not far from 17,500,000,000 gallons now, and the operating expenses of the works are about 372,000 dols. a year. The new works, which are not yet completed, will cost a large sum, and the commissioner is naturally averse to propose the expenditure of another large sum for a filtering plant until he is sure that the system which he recommends is that best adapted for the city. Owing to the large amount of sediment in the raw river water the filtration becomes more difficult than were it free from the earthy matter. The amount of sediment in the water can be suggested to the reader from the fact that in one year over 210,000 cubic yards of this matter was removed from the settling basins at Bissell's Point. Mr. Holman is now conducting experiments to ascertain if he can keep sand filters free from clogging by a reversal of flow through the beds so as to wash them. He is also conducting experiments with carbon plates and with tripoli stone from a quarry in Carthage, Mo., which is porous like the artificial stones used in works for filtering the Rhine water.

THE *St. Louis Republic* says :—Near the little village of San Jose, Peru, on the shores of the great lake of Titicaca, the most lofty lake in the whole known world, are three pillars of stone of unequal height. On one of these huge blocks the rude features of a human being have been cut, and the other two are covered with designs of various kinds, all believed to have some mysterious reference to sun worship. Who the engraver

J. ATTWOOD.

STOURBRIDGE.

The only Attwood in the Trade.

of these monoliths was or at what age of the world the engraving was done is not known, but it is highly probable that it was done long before the Americas had ever been seen by any white man.

Stone of Indianapolis says:—At Webster City, Iowa, a ten-acre tract of as handsome hone stone as can be found in the world has just been discovered in Hardin county, about twenty miles east of here and two miles from Iowa Falls. Fifty cars of hone stone are in sight at the bed. The stone found in this bed has been tested by New York experts, and they pronounce it equal to that mined in Asia Minor.

AFTER the fashion of *Stone*, a periodical entitled *Brick* has been started in Chicago, and has reached its sixth number, which is just to hand. American engineers are instructed by one who does not sign a name as follows:—"I don't believe much in paving brick tests anyhow. They are mostly wrong, dead wrong. Now take the absorption test. A paving brick must not absorb more than two, or at most three, per cent. of moisture and if it takes less than that so much the better. I say that if a city engineer really knew anything about brick he wouldn't take a paver at any price that was absolutely non-absorbent. Why, sir, he might just as well put down chunks of glass in the street for horses to skate over." A good paving brick must be porous; of course it must not hold so much water that when the frost comes it splits the bricks in all directions. A paver that absorbs five per cent. of water is better than one which can only hold half that quantity. Now about the rattler test. If ever there was a misleading, useless test that's the one. It's supposed to show the wear of a pavement 'attrition' the engineers call it. What do we need to know about that? What we want is a hammer test." The writer of the note is probably an ironmonger.

CAISSONS v. DOCK GATES.

AT the meeting of the Civil and Mechanical Engineers' Society held on the 3rd instant, a paper was read by Mr. A. W. Ackermann, entitled "Caissons v. Dock Gates." He gave a concise history of caissons, which were apparently first used in France at the port of Rochefort in the year 1728 A.D. There is, however, some evidence of their having been used at a much earlier date by the Venetian Republic. General Bentham first introduced them into England for use in H.M. Dockyard, Portsmouth. The early caissons were constructed of wood

and heavily ballasted. Iron caissons were first used at H.M. Dockyard, Woolwich. No great improvement in their design took place until 1865, when the extension works of H.M. Dockyards, Chatham and Portsmouth, were undertaken by Sir Andrew Clarke, R.E., K.C.M.G., Director of Works for the Admiralty. The principles involved in designing caissons were explained. The advantages of caissons over dock gates were forcibly pointed out. The difference between ship and sliding caissons was clearly described, together with numerous details of their construction and the machinery used in connection with them. The paper was illustrated by large scale diagrams.

REVOLVING LIGHTS.

WE have from time to time noticed several improvements in lighthouse illumination introduced by Mr. J. R. Wigham (Edmundson & Co.), of London and Dublin. He has recently invented a new lighthouse light, and has brought it experimentally before the science department of the Royal Dublin Society. It may be briefly described as a method of making the illumination of revolving lights continuous, instead of as at present recurrent after intervals of darkness. A boon to navigation which mariners have very earnestly desired is that they might have the benefit of the great power and characteristic appearance of revolving lights and at the same time have them continually in their eye as are the fixed lights round our coasts. Mr. Wigham has had long experience in lighthouse matters, and this invention of his is considered the greatest advance which has been made in the science of lighthouse illumination since the time of Fresnel. Mr. Wigham's previous inventions, which have been adopted to a considerable extent by lighthouse authorities, have been mostly in the direction of conferring increased power on lighthouse illuminants. This new invention supplements those which he has previously made, inasmuch as it is applicable to all lighthouse lights—gas, oil, and electricity.

BUILDING IN THE DUNDEE DISTRICT.

AT a time when many branches of local industry are suffering from a severe depression it is pleasant, says the *Dundee Advertiser*, to be able to point to one department of labour which can boast of its flourishing and prosperous condition. Such has been the state of the building trade in Dundee during the past twelve months. In the early months of the year prospects were by no means bright, and a dull season was expected, but when Whitsunday was passed contracts came out in surprising numbers. At Midsummer building was going ahead briskly all over the city, and since that period the trade has been fully employed. The feature of the year's work has been the large number of dwelling-houses that have been put in the hands of the builders. In explanation of this circumstance it is said that many persons who have in hand money which they are desirous of investing prefer to sink it in property at home rather than run the risk of losing it in foreign or colonial ventures, and in the carrying out of their desire they are assisted by the cheap rate of interest at which money can now be borrowed. Whether this is the real explanation, or whether it is to be attributed to the natural extension of the city, the fact remains that the past year has been exceptional in the amount of tenement work which has been, or is being, carried out. Building of a more public character has been scarce. Masons have been in demand during the whole year, and more especially since Whitsunday. It appears that at the present time there is a scarcity of this class of skilled workmen in the city. For a number of years the master masons had shown a disinclination to engage apprentices, but this policy they have now changed, and the yards have been stocked with young men, so that in the course of time the difficulty referred to should pass away. Wages have remained unaltered during the year, viz. 8½d. for builders and 8d. for hewers, this arrangement continuing in force until April.

The outlook for the coming year is bright. Already a number of large works are on the list, including the new post office, the new co-operative bakery, Mr. Aitken's property in Miller's Wynd, and a probable extension of the public baths. Many of the "jobs" on hand at the end of last year will extend far into the next, so that the prosperity which has attended the trade of recent months may be expected to continue for many months to come.

Building operations in Broughty Ferry during the past year have consisted entirely in the erection of dwelling-houses of

various classes. On the old Hermitage ground, which has now been feued, numerous dwellings have been or are in course of being reared.

In Newport, and especially in Wormit, the building trade has been exceptionally brisk.

BUILDING IN BOLTON.

LIKE many of its predecessors, the year just closing has, says the *Bolton Chronicle*, been a period of considerable activity in regard to building operations in this borough and the neighbourhood. Including the completion of undertakings commenced previously to the advent of 1894 and the work still in hand by Bolton architects and contractors, the list of structural extensions and renovations assumes formidable proportions in the aggregate, and also shows great variety. A few new mills are in progress, and additions have been made to existing mills, manufactories and other industrial or trading concerns; one or two new places of worship are in hand; mission room and school accommodation has been added to; new shop building has been carried out extensively; and other structural work which the enterprise of the age has necessitated or suggested has received much development. One particularly notable feature has been the growth of dwelling-house erection; vacant spots in different quarters, but chiefly on the outskirts of the town—the Mortfield estate, Brownlow Fold, the neighbourhood of Back-o'-th'-Bank, Daubhill and Gilnow—being gradually occupied in this way; the houses are principally for the artisan and labouring classes, and generally the style of these blocks is attractive and the interiors commodious.

PORTLAND CEMENT.

If we may judge from certain letters in the architectural and engineering press, says Mr. G. A. Redgrave, and from the meeting of manufacturers which was recently held at the Cannon Street Hotel, the Portland cement trade—one of the most important industries in the London district—is threatened with innovations calculated to do the most serious injury, alike to those engaged in the production of this material, and also to all those who make use of cement. It is urged on behalf of

NEWCASTLE-ON-TYNE.

certain manufacturers that it is necessary to form an association of English Portland cement makers pledged to avoid all mixtures of less valuable ingredients with the cement after calcination. This step they affirm to be imperatively needed, because certain cement dealers in the London district are in the habit of cheapening their cement by grinding up with the "clinker" (the product as it comes from the kilns) a considerable percentage of Kentish ragstone—a hard, inert substance of comparatively trifling value. From statements made by those well acquainted with the trade the cost of making Portland cement is reduced by this practice as much as from 2s. 6d. to 3s. 6d. per ton, and this amount, therefore, goes into the pockets of the producers, for no proposal has been made hitherto to sell this mixed material at a lower price than genuine Portland cement.

The possibility of adulterating cement in this way is mainly due to the defective tests which suffice in this country to satisfy users of cement, but it is alleged also that we have no official and generally-recognised definition of the term "Portland cement." A well-known firm, which makes no secret of its use of ragstone, maintains indeed that "Portland cement is only the name for an article of admixture," and founds thereon an argument for the incorporation with the cement of "an ingredient whose beneficial action has only lately been discovered." I have long foreseen the probability of the events now taking place, and in a paper which I prepared in conjunction with the late Major-General Scott, C.B., and which was read before the Institution of Civil Engineers more than fourteen years ago, we stated that we trusted that "engineers would agree in declaring that the time had arrived when a uniform scheme for the testing of Portland cement could be drawn up and a standard scale of tests could be adopted throughout the country." In Germany, where the process of mixing cements with slag, powdered limestone, slaked lime, and other adulterants was at one time largely and skilfully practised, it has been found possible, by the adoption of standard tests and by the formation of a powerful association of manufacturers, to stamp out this vicious system. It was conclusively proved at that time, now about ten or twelve years ago, that all these substances, added to the cement subsequent to the calcination, had the effect of diminishing its value *qua* cement, and in those cases where small quantities of extraneous ingredients appeared to increase the tensile strength of the material it was shown that this apparent gain was really due either to defects in the method of testing the cement or else to imperfect grinding.

It is in both of these directions that our own system is at

fault. English cements at the present time are in the great majority of cases insufficiently ground, while the tests of neat cement which are still in general use fail to indicate the presence of large percentages of coarse unground particles, which are of no more use than an equal bulk of sand.

Careful tests have convinced me that none of the grains of cement which are retained on an 80-mesh sieve are of any cementitious value, whereas it is the common rule in England to specify not more than 10 per cent. of residue on a 50-mesh sieve. It is the presence of these coarse particles in most cements which enables manufacturers who grind their cement rather finer than do their neighbours to introduce considerable percentages of cheap inert substances without detracting from the quality of the product, as indicated by the tests in common use, while the absence of a definite understanding about the composition of Portland cement opens the door to what German manufacturers have stated to be "a fraud upon the consumer." Throughout Germany Portland cement is declared to be "a material resulting from an intimate admixture of lime and clay as its essential components, calcined to incipient vitrification and reduced to powder."

BUILDING IN ABERDEEN.

FROM its variety of industries Aberdeen was favoured with a marked degree of prosperity during the year. Some trades were less fortunate than others, but, taken all over, the general depression experienced in southern centres was not felt to the same degree in the Granite City. The condition of the building trade, says the *Scotsman*, may be taken as a fair criterion of the state of business in the city, and in this department of work the activity was of an unusually vigorous character. No fewer than 377 plans of new houses were sanctioned, representing a total value of 257,280/. In the previous year 251 houses were put up. The city has vastly extended in all directions. Handsome new thoroughfares are cropping up in the suburbs, and the large number of new public and private buildings which have recently made their appearance very greatly enhance the architectural aspect of the streets. Glancing at what has been overtaken during the year, the extension of Marischal College was pushed on, but the work of erecting the Mitchell Tower has been discontinued until spring. A new public school at Broomhill is approaching completion, at an expenditure of about 8,000/. or 9,000/., and improvements and extensions were carried out on a large

number of other educational institutions. A new church was built for the Free Holburn congregation in Great Western Road, costing about 5,000*l*, and another church was erected for the Baptist congregation at Rosemount Viaduct. In course of construction is a new church for Bon-Accord Free Church, at a cost of about 5,500*l*, and an Established church at Cleave-the-Wind, at an expenditure of 2,500*l*. The extension of the Royal Lunatic Asylum has been in progress, and the work is estimated at 20,000*l*, while the City Hospital enlargement, estimated at 13,000*l*, is nearly completed. New police buildings in Lodge Walk, to supersede the old prison, are finished, and these will cost about 10,000*l*. A prominent structure at the east end of Castle Street (the Salvation Army Citadel), estimated at 13,500*l*, is well advanced. The extension of Trinity Hall, belonging to the Incorporated Trades, formed a notable feature of architectural rearrangement. In Union Terrace a handsome new savings bank is to be erected at an outlay of 10,000*l*. The Sailors' Institute in James Street has undergone large additions and alterations. A new public soup kitchen was opened in Loch Street the other day. In Guild Street the Great North of Scotland Railway Company occupied this year a large administrative block costing about 12,000*l*. A new hotel is in course of construction in King Street. In Rosemount, the Northern Co-operative Company are erecting a large block, the expenditure being 7,000*l*; and in the same vicinity, Rosemount Avenue, the Foresters are putting up an extensive block of dwelling-houses. The number of private dwelling-houses erected in the city during the year was quite phenomenal, the total being 252, or sixty-eight more than last year, the value increasing from 126,855*l* to 180,685*l*, a rise of 53,830*l*. Turning to a staple industry, the granite trade, operations were fairly active. Dulness was experienced in the monumental department on account of depression in the American exports. The larger firms were busy with contracts in the form of polished fronts for buildings, and this branch of the industry is reported to be steadily increasing. There is a demand among architects for polished granite fronts to large buildings, and many orders of this description were executed for cities in England and Ireland, besides the manufacture of polished counters and tables for restaurants and hotels. In the granite trade generally complaint is made of the "cut" prices and keen competition. The export trade with America shows that during the first nine months of last year the value of manufactured granite sent from Aberdeen amounted to about 69,000*l*, while during the same period in the present year it fell to

44,700*l*, a reduction of 24,300*l*. It is confidently anticipated, however, that business will take an improved turn, and already the orders booked for spring are on the increase. The reduced tariff may have something to do with this. A notable circumstance is the large decline in connection with the imports of foreign granite, particularly the Norwegian material, to Aberdeen, which is mainly worked into monuments for the American market. In 1893 as much as 13,700 tons were brought to the city, the harbour dues on this item alone bringing 285*l*, while during the past year the imports fell by more than 5,000 tons. The total imports came to 8,224 tons, the dues realising 171*l*, the decline in quantity and value respectively being 5,476 tons and 114*l* dues. The home quarries were affected to a certain extent by the dulness in the monumental trade, but the output was reported larger at most of the principal quarries. An unlimited supply of fine stone is available. Messrs. Alexander Macdonald & Co. executed several commissions for the Queen, both for Balmoral and Windsor, and are at present carrying out the contract for Crathie Church pulpit, which will be a chaste work of art composed of about a dozen different Scottish granites. The same firm did good business in quarrying and general manufactured work, the latter including several fountains, pedestals and memorials. Mr. James Hutcheon, Hill of Fare quarries, secured the contract for the granite work of the new bridge across the Kelvin at Glasgow. Mr. John Fyfe's quarries were fully and briskly employed. Messrs. Whitehead & Sons were busy with contracts for polished granite fronts and monumental work, and the same encouraging business was done at the other Peterhead quarries. The manufacture of the new material, adamant stone, by Messrs. A. & F. Manuelle, gives promising results.

THE LITIGATION OF THE LONDON COUNTY COUNCIL.

A CORRESPONDENT of the *Times*, who has justified the title he assumed, "One Who Knows," sends the following remarks on the litigious spirit of the London County Council:—

We are a patient people. But there is a point beyond which even the most stolid patience refuses to be pressed. What are the feelings of London ratepayers, as half-year by half-year they find the local rates growing in amount, and their attention drawn by the vestries to the fact that this increase is due to the London County Council? In my own case I pay

now every half-year considerably more, much more, than I used to pay in the year, and my case must be that of every householder. Do I, as a citizen, reap in improvements and extra accommodation an adequate compensation for this extra and steadily-growing burden? I cannot find that I do, and most householders, I believe, will tell the same story.

It is a matter of course that a County Council mainly composed of faddists, who call themselves Progressives, should pay no heed to the expense involved in carrying out their views. It is not upon them that the burden falls; and it is delightful to be free to have a rating power at command for one's experiments on political economy and in legislation.

Take legislation as an example. Will any member have the courage to ask for a return of the number of Bills promoted by the London County Council during the last five years, of those that have been passed, of those that have been rejected in whole or in part, and of the costs the ratepayers have had to pay for their promotion? It will open a good many eyes to an abuse which it is high time to check; for the grievance does not merely lie in the money thrown away by the County Council, but quite as much in the enormous cost to which individuals and corporate bodies are put in defending their interests against invasion or encroachment. I deliberately say "enormous," having in my professional capacity had occasion to mourn over the ruinous expenses to which my own clients have been put in this way. My fellow-professional brethren can tell the same tale. They may have defeated the County Council, but at what an expense! The autocrats of Spring Gardens care nothing for this; indeed, as we professional men know, they conduct their Parliamentary campaigns as if it formed part of their tactics to cause as much delay as they can, and to weary out their opponents by aggravating the expense of a warfare which is always heavy at the best. The same policy governs their interference with the Bills promoted by other people. "No man's pie is free from their ambitious finger;" and demands are made for the insertion of absurd clauses in Bills which have to be fought out in committee, and generally defeated by the usual costly machinery of counsel and witnesses. Parliamentary Q.C.'s may rejoice at this, but what of the unhappy clients? It is of no use to say to them, "Swear not at all." In curses both loud and deep they denounce the hour that gave birth to the London County Council.

Nothing apparently delights that body more than to go on the war-path. They have slain the tramway companies; and

now the trumpet of defiance to the water companies, which they have blown so long, sounds a deadly charge against them, heralded by no fewer than eight separate Bills. If these ever reach committee, they will involve the ratepayers in costs which it is simply alarming to contemplate. If they succeed—a result certainly doubtful—the consequences to the community, it would not be difficult to show, will be still more alarming.

The County Council have hitherto failed to persuade Parliament that they should have the control of the water supply of London. A body more unfit for such an office could scarcely be imagined. When Mr. Cross introduced his Bill for the purchase of the water companies, after the most anxious deliberation, it was determined that to a public trust, in the hands of skilled men of high standing and responsibility to Parliament, could alone be confided a responsibility so great. Only then would the possibility be excluded of jobbing in patronage, and of the manipulation of votes which the employment of a vast number of officials and workmen would place in the hands of any other body. Before embarking in such a conflict with the water companies as that threatened by the County Council, surely the fitness of the Council for the trust should have been first debated. If affirmed, then they might with some grace have come to Parliament for powers to purchase. But until affirmed, what justification can there be for introducing eight different Bills to enable them to deal separately with the eight different companies?

One other important principle governed Mr. Cross and his advisers. It was this—that if any improvement in efficiency or economy was to result from buying up the water companies they must all be bought up. So the cost of separate boards and separate officials could be got rid of, and the powers of certain of the companies be interchangeably used to distribute the supplies more equally and at the smallest cost. If this were so in Mr. Cross's time, are things different now? Certainly not. Without having all the companies in one hand no adequate return can be hoped for the inevitable risk and cost which must be involved in taking over their eight separate undertakings. And now the County Council ask for powers in eight separate Bills to compel the companies to part with their undertakings.

And on what terms are they to be bought? If no agreement is come to—and it requires no prophet to tell us that none will be come to—then the terms are to be settled by arbitration. Arbitration! Who that knows what arbitrations for compulsory purchase are but must shudder to think of the waste

of time and money that will be spent over arbitrations where the property to be taken runs into a figure over thirty millions? Mr. Cross, being a man of business and strong common sense, knew well that to deal with the water companies in this way was hopeless. He therefore took the course of agreeing with them, after lengthened negotiations conducted on his behalf by the late Mr. Edmund Smith, a man not to be equalled now in capacity for so great an undertaking. Mr. Smith succeeded in obtaining terms which satisfied the companies, but which, unhappily, did not satisfy either the Corporation or the Metropolitan Board of Works, both of which bodies were furious at the prospect of the ambition being defeated which they had each long cherished, of getting the control of the water supply into their own hands. It is useless to recur to the melancholy tale of the use made by Sir William Harcourt and his party of the opportunities thus afforded them to strike a blow at Lord Beaconsfield's Government. The arrangement with the companies was negatived, but it soon afterwards became apparent that Mr. Smith was right in all his calculations. The prospective increase in revenue on which they were based was very quickly more than realised, and the community lost not only a large increase upon the market value of the purchase, but all the advantages which would have resulted since 1880 from concentration of management by a body of trustees, above selfish influence, with only the welfare of the Metropolis to consult. So was London sacrificed to party politics.

It is more than doubtful if what was then lost can ever be retrieved. At the same price I am convinced the undertakings can never be acquired, for their value has increased greatly since 1880. I observe from Mr. Beachcroft's letter in your paper of to-day, that he is much of the same mind; and, at any rate, he does not see where the money for the purchase is to come from. That essential was well considered and provided for in Mr. Cross's scheme. It would have imposed no appreciable burden upon the ratepayers. Indeed, under his scheme, had it been carried, there would by this time have been no burden at all on the ratepayers, and the price of water to the consumers would have been sensibly lowered.

Meanwhile, to those ratepayers who know what a fight with eight powerful companies means, the vista opened up by these eight Bills of the Council is anything but agreeable. The water companies, well drained already by the Parliamentary contests in which the County Council have involved them, can still afford to fight them without appreciably, perhaps, diminishing their means. But it will be a battle of the giants—and

who will suffer? Not the self-opinionated gentlemen who would place the Parliament of Spring Gardens above Queen, Lords and Commons, but we, the unhappy citizens, who find already our local rates more than we can bear. Let these things be remembered next March, when they will have an opportunity of returning men with a deeper sense of responsibility and more moderate ambition.

BUILDING LAND AT SALTLEY.

AN important arbitration case has been heard by Mr. Under-Sheriff Heath in Birmingham. The Trustees of the Hutton Estate claimed 25,000% from the Midland Railway Company for the compulsory taking of lands and for severing and injuriously affecting adjoining lands situate at Nechells and Saltley. The estate has an area of over eighty-nine acres, and is at present leased to the Tame and Rea Drainage Board, part of it being devoted to the purposes of the sewage farm. It was urged for the claimants that, owing to the isolated position of the estate, the preservation of a certain approach from Church Road, Saltley, was vital to its prospects as building land, and that, access from this point having been interrupted by the railway company, the value of the estate had suffered depreciation to the amount of 21,381%. One of the main questions for the jury was whether the estate had any prospective value as building land, and there were several minor points in dispute between the parties, apart from the legal considerations involved in the case. The estate was originally leased to the Birmingham Corporation in 1867 at 7% per acre per annum, and on the constitution of the Drainage Board it was transferred to that authority. The lease expired in 1889, but was renewed, the price being reduced to 5% 6s. per acre. Stress was laid on the fact that there were certain reservations in the leases as to the landlord resuming possession of a portion of the land for building purposes at short notice.

Mr. Lister Lea, surveyor to the estate, stated that the land was admirably adapted for the erection of warehouses and factories, the immediate contiguity of the railways and canal affording exceptional facilities for transit. He maintained, however, that the approach by road which the Midland Railway Company had blocked was essential to the development of the estate. He estimated the value of the estate for building purposes at 58,000%, and stated that it was in contemplation to offer the land for building sites when a favourable time arrived.

Illustrated PRICE LIST on application.

An opportune occasion had not arisen for eight or nine years past, or the claimants would have availed themselves of it. Whilst recognising that the sewers on the estate would have to be dealt with before buildings could be erected, he did not anticipate any serious difficulty in that respect, nor did he think the fact that the land had been used for sewage-disposal would be prohibitive.

Mr. Mason (Messrs. Hedley, Mason & Hedley, surveyors) also agreed that the estate had a prospective value for building purposes, and expressed the opinion that it would be ripe for building in fifteen years if Birmingham continued to grow at the same rate as it had during the past fifteen years.

Mr. Christopher Oakley, a London surveyor, admitted that there were special difficulties in the way of developing the estate for building, but did not regard it as unadapted to the purpose. The approach through the 50-feet archway he considered all important.

Mr. T. S. Fallows (mayor of Birmingham) gave it as his opinion, as a surveyor of long experience, that when the present lease had expired the land in question would be fit for development as a general building estate. Anyone who knew the neighbourhood was well aware that houses and works had advanced quite close to the estate. He considered that in eighteen years the value of the land would be 800*l.* an acre—that was 2*d.* per yard leasehold, which he thought was a very low figure to put it at. The closing of the access at the south end would completely ruin the property for building purposes, and the blocking up of the archway would depreciate its value by two-thirds, or 533*l.* an acre. Evidence on behalf of the Midland Railway Company was then given.

Mr. William Martin (Messrs. Martin & Chamberlain, architects and surveyors, Birmingham) said he regarded the larger portion of the estate to the north of the London and North-Western Railway as purely agricultural, and as possessing no prospective building value. In cross-examination he admitted that some thirteen years ago he drew up a plan showing how that part of the estate within Saltley might be cut up for building purposes, but at the time he was unaware of the rights attached to some of the easements, and he had since found there were legal obstacles to the construction of a road on which the scheme hinged. The estate was divided into small plots by the sewers and watercourses which intersected it, and it was his conviction that it was no nearer development as a building estate now than it was twenty years ago.

Mr. George Matthews also gave evidence to the same

effect, and said the accommodation works proposed by the railway company were adequate for the estate as agricultural land. He had no doubt a plot of land here and there might be let for building, but what he questioned was whether, as a whole, it would be worth the expense involved in laying it out.

Mr. John Wilmot (Messrs. Wilmot, Fowler & Wilmot, surveyors) expressed a similar opinion.

Mr. John Macdonald (engineer-in-chief to the Midland Railway Company) explained that it had been found necessary to take a portion of the claimants' estate to the south of the London and North-Western Railway in consequence of the doubling of the lines between Derby and Birmingham and the abolition of the level crossing in use at Saltley. The railway company were prepared to make accommodation works providing adequate access to claimants' property. This completed the case.

Mr. Bidder, in addressing the jury, characterised the claim as being made up of reality and romance—the reality being measured by hundreds of pounds and the romance by tens or thousands. Although the Midland Railway Company had taken the strip of land across the mouth of the arch which claimants contended was the essential approach to the estate, it was obvious that their object was to continue the road under that arch; but the claimants had rejected all proposals with regard to accommodation works, and had insisted on getting their pound of flesh. He submitted that the land on the north of the London and North-Western had no prospective building value, and it was consecrated to the deposit of the sewage matter of Birmingham to all ages.

Mr. Jelf replied, urging that the great weight of evidence was in favour of the view that the estate was adapted for building purposes, that it was conclusively established that it had always been in contemplation to apply it to that purpose, and that the action of the railway company must indubitably have a very detrimental effect on its value.

The Under-Sheriff having summed up, the jury retired, and an hour and a quarter elapsed before they returned with a verdict. Their finding was that for the two pieces of land compulsorily taken the railway company should pay 33*l.* and 450*l.* respectively. They awarded 280*l.* as compensation for injury done to a strip of land on the south side of the London and North-Western Railway; and with regard to the larger question concerning the seventy-seven acres of land to the north of the railway, they found that it had a remote building value, and assessed the damage sustained by the claimants at 2,125*l.*

London Office and Showrooms:—9 SOUTHAMPTON ROW HOLBORN, W.C.

THE STOCK EXCHANGE, BOSTON.

WE publish below an illustration of a stairway and hall in the Exchange Building of Boston, Peabody & Stearns, architects. This building was completed last December and is located in the financial centre of the city. It is the home of the Stock Exchange, several national banks and numerous brokerage firms. The stairway is in the centre of the grand hall which leads directly to the floor of the Stock Exchange. It is of Bardiglio marble, a greyish-white with veinings and mottlings of a dark grey, which has a very high polish. At the top of each newel post is a globe held from rolling off its perch by four clusters of honeysuckle beautifully carved in high relief. A skylight of enormous proportions illuminates the hall and stairway, and also becomes the illuminating ceiling of a large banking-room. It is of wrought and lattice-iron and copper framing, in which is set ground-glass panels five-eighths of an inch in thickness. It is painted white, and the walls, which are in plaster, are painted a yellowish buff, but the pilasters which support the arches are creamy in hue, and the archings over doors and windows are still lighter, making a colour gamut of delightful freshness, harmonising with the Bardiglio marble used for stairway and for the flooring and wainscoting. The doors and windows are of mahogany, which gives the positive accent needed.

THE GENERAL POST OFFICE NORTH.

THE new building in St. Martin's-le-Grand, which will be known as the General Post Office North, stands upon about an acre and a quarter of ground, the cost of which, exclusive of that part at the north-eastern end where stood the old Money Order Office, has been 326,200*l.*, while it is estimated that the building itself will cost altogether as much as 200,000*l.* On plan it is somewhat irregular, the eastern front, facing St. Martin's-le-Grand, being considerably larger than the western front, which faces King Edward Street. In both fronts are archways opening directly into a courtyard which runs right through the building, while the doors giving access to the interior open from each side of the archways. The St. Martin's-le-Grand entrance will be that mostly used both by

the officials and the general public. The building is five storeys in height, but the last is only partial, and will be devoted to kitchens and refreshment-rooms. There is also a large and well-lighted sub-ground floor available for clerical work, while below that there is a spacious basement extending under the whole building, including the courtyard, which is admirably adapted for storage. The interior of the new post office is effectively arranged. In the corridors the flooring is of stone mosaic, while wood parquet flooring is to be found in all the larger rooms. A feature of the internal arrangements to be noticed is the vast rooms on the third and fourth floors respectively. There are two such rooms, each measuring about 100 feet long by 45 feet wide, on each floor, lighted on the one side from the courtyard, and on the other from the street, and each room will accommodate, it is said, no less than one hundred clerks. Apartments have been set apart at the south-west corner of the building on the ground and first floors for the use of the Postmaster-General and the Secretary. It is calculated that altogether the new building will accommodate about 2,000 persons, comprising the Postmaster-General, the Secretary, the Solicitor, and the Receiver and Accountant-General, and their respective staffs, all more or less numerous, while the whole of the fourth floor is to be devoted to the female staff employed in the postal order branch, numbering over 300 persons.

The general arrangements of the interior of the new General Post Office are in every respect complete as regards the comfort and convenience of the staff. Not only are there several staircases, but the various floors will also be connected with lifts, of which we believe there are to be no less than four, thus securing a maximum of speed with a minimum of fatigue in the general intercommunication of the various branches of the Department therein located. The principal passenger lift, it should perhaps be remarked, will be worked on the hydraulic ram principle, the ram descending into a well 75 feet deep. A curious feature of the roof of the new building is a well marked tennis court, which is supposed to have its origin in a playful suggestion of one of the postal authorities that, being quite flat, the roof appeared well adapted to this popular summer game. The new Post Office has been designed by Mr. Henry Tanner, surveyor of Her Majesty's Office of Works.

THE BLACKWALL TUNNEL.

THE problem of joining the two banks of the Thames below London Bridge has occupied the attention of engineers for many years past. In the first year of this century (says the *Times*) an attempt was made in this direction by means of a tunnel, and twenty-four years later Brunel's great work was commenced. When the Thames Tunnel was built there was open country—meadows and marshes—as soon as Bow Bridge was crossed and the traveller had passed from Middlesex to Essex; indeed, fields and country lanes extended almost up to the confines of Whitechapel. Now Stratford, which for years later possessed the characteristics of an outlying country town, is the centre of a densely-populated district extending for miles in each direction; whilst further east still are whole colonies of suburban residences, closely packed, where, in Brunel's day, stood isolated villages surrounded by tracts of forest and meadow land. Much the same may be said of the Kentish side; and there are now continuous lines of factories, wharves and docks as far as Barking on the north and Woolwich on the south bank of the river. All this vast district, equal in area and population to two large towns, is, as Brunel left it, cleft in twain by the river. It is to link these two important eastern limbs of the Metropolis that the Blackwall Tunnel is now being constructed.

The site of the work is in the bight of the Thames formed by Blackwall and Charlton reaches. On the Middlesex side the northern approach connects directly with the East India Docks, close to the chief entrance, and on the Kentish side the tunnel leads to the desolate peninsula to the eastward of Greenwich. The total length of the tunnel and its approaches is 6,200 feet, of which 1,735 feet consist of open approaches. The roadway is 16 feet wide, with 3 feet side-walks, in addition to which extensive roads leading to it are being constructed. At the present time the work has been in progress somewhat under three years, and possibly it will take two more years before it is complete, although subaqueous work is always uncertain. The river tunnel will be approached by an inclined roadway on each side, partly open cutting and partly tunnel, up and down which the vehicular traffic will have to ascend and descend. The gradient averages 1 in 35, which is about the steepness of St. James's Street.

In carrying out the work there have been constructed four large vertical shafts, two on each side of the river. Two are of 98 feet, one of 75 feet, and the other of 76 feet deep. They are in

themselves, considered apart from the other work, important structures. At their lower ends they form points of departure for the tunnelling operations.

Water is, naturally, the great enemy of the subaqueous tunnel engineer, and in the case of the Blackwall Tunnel the difficulties encountered will be of more than ordinary magnitude. In order to meet these the engineers have had recourse to the Greathead shield, so-called after its inventor, the well-known engineer of that name. It may be briefly described as a strong cylinder or tube of steel, approximately of the diameter of the tunnel to be made. In the present case it is 27 feet 8 inches in diameter and 19 feet 6 inches long. About half-way in the length of the cylinder are placed two bulkheads or diaphragms made of stout steel plates, there being a distance of about 3 feet between them. The shield, having been erected beneath the surface at the depth required to commence the boring—the parts having been lowered down the vertical shafts previously excavated—the following method of working is followed. The cylindrical shield is of course on its side, that is to say, its axis is always parallel with the line of advance. The workmen pass through doors provided in the diaphragms and at once attack the face of earth exposed at the end of the cylindrical shield. It should be explained that the part of the cylinder forward of the diaphragm is divided up into twelve cells or working compartments, just as a house is divided by its rooms and storeys. This enables the workmen to reach the whole face at once. The earth is removed by ordinary means, and is passed through the diaphragm to be carried by trucks to the shaft, where it is carried to the surface. Whilst the excavation is going on in the fore part of the shield the tunnel itself is being erected in the tail part at the back of the diaphragm. The tunnel lining consists of massive segmental iron castings, which are bolted together. A suitable length of the tunnel lining thus being built up inside the shield—in the position it will occupy when the whole work is completed—and a corresponding length of ground having been excavated in front of the shield, it becomes necessary to move the shield forward. In order to do this there are twenty-eight hydraulic rams, which are fixed horizontally round the inner circumference of the shield. Their rams point to the rear of the shield, and when these are forced out, by the admission of water at pressure, they press against the completed ring of tunnel lining, the total pressure being 2,800 tons. In this way the whole shield is forced forward into the hole excavated, leaving the completed ring of the tunnel behind it—that is to say, the cylindrical

shield is drawn off the tunnel lining just as the outer tube of a telescope slides off the smaller one within. It has been said that the shield slides forward into the space excavated to receive it; but, as a matter of fact, the forward edge or rim of the shield is made to form a cutting edge, and as the rams press the shield forward this edge is forced into the earth, thus making the hole exactly to the shape of the shield. The whole of the earth displaced has, however, to be removed to the back of the diaphragm by the workmen. When the shield has been moved forward the hydraulic rams are withdrawn into their cylinders again, and thus space is exposed for a fresh ring of lining to be erected, and the operations are thus continued by intermittent stages. Cement grout is forced through holes in the iron lining, and, when set, forms an outer coat to the lining, occupying the space vacated by the shield when it slid forward.

So far we have described the operations pursued when working in firm soil, but even in this case the shield offers great advantages, though its virtues are not so manifest as when difficult water-bearing strata are reached. It will be seen that in any case the workmen are protected by the shield from any fall of material, and for this reason the extensive timbering necessary to support the superincumbent weight of earth is avoided. The work on the Blackwall Tunnel will by no means all be of this rosy nature; indeed, the construction of the tunnel will, if successfully completed—as doubtless it will be under the present vigorous management—form one of the most notable feats of boring through watery soil in the annals of engineering practice. It will be seen that at the working face where the soil is exposed, water would be able to find its way into the shield were there any large quantity percolating through the strata operated upon. In constructing the tunnel the work will have to be carried for a considerable distance through a bed of loos gravel and sand, of which there will be no more than 7 feet between the crown of the working and the river bottom. Through this the water from the river, sometimes with a head of 47 feet, would pour in such copious streams that the workings would soon be drowned out were not special means taken to prevent it. Fortunately the practice of tunnelling in water-bearing soils has made great strides in recent years, and these means are at hand. They consist of forcing air at considerable pressure into the part of the shield where the excavators work in front of the diaphragm. In sinking the foundations of bridges, or other structures in loose soil with a head of water above, the use of compressed air is

not uncommon, but there the working is in a vertical direction, so that the method of operation is easily to be understood, the air being imprisoned as in a diving bell. In working horizontally, however, the same conditions do not apply. The air, of course, must be constantly escaping at the face, and in this way it partially blows back the water filling the interstices of the soil. A bed of clay, consisting of many thousands of tons, will be tipped into the bed of the river from barges, to obstruct further the ingress of water. The depth from high-water level to the bottom of the tunnel will be 80 feet, which is equivalent to an air-pressure of 35 lbs. to the square inch. Although this is high, it is not beyond the endurance of men suitably constituted for such work. We believe 48 lbs. to the square inch is the highest pressure at which men have been known to carry on operations of this nature, and in that case only two hours' work out of the twenty-four hours was possible.

On the whole, it will be seen that the work now being carried out upon the Blackwall Tunnel is of more than usual difficulty, and its prosecution will be followed with interest.

Mr. A. R. Binnie, the engineer to the London County Council, is chief engineer to the work, Messrs. David Hay and Maurice Fitzmaurice being resident engineers. Mr. J. H. Greathead is consulting engineer for the subaqueous and tunnelling work. Messrs. Pearson & Sons are the contractors, their tender amounting to 871,000*l*.

THE NEW ADMIRALTY OFFICES.

THE westerly block of the new Admiralty Offices has so far advanced towards completion that it will be ready for permanent occupation early in the new year, and plans for the eastward block are in hand. Along one side of the quadrangle, fronting the Horse Guards Parade, a double columnar stone screen will connect the new with the old building, forming a covered footway for the use of officials, while underneath will be a subway for internal communication. The design of the new building is a fenestrated type of Italian Classic architecture, three-quarter columns being introduced at salient points to afford appropriate relief. Careful consideration has been given to the skyline, with the result that, while adopting Classic detail, picturesque effect has been obtained, each feature of ornamentation being utilised for practical purposes, such as those of ventilators and water tanks.

The structure is placed in what may be termed a "dry dock," built up from the London clay in solid concrete, and encased with asphalt so as to insure perfect freedom from damp. This portion of the work was very difficult and necessarily costly, a sum of 23,000*l.* having to be expended before any portion of the building proper could be undertaken. The foundation is in marked contrast with that of the old building, the latter having a foundation of oak planking and sleepers, laid directly on the old river bed. The extra cost is not, however, wasted, as by the arrangement thus carried out two storeys of rooms, perfectly free from damp, have been obtained. The accommodation in the building is much larger than appears from the outside, no less than six storeys of office rooms, repositories, and strong rooms having been secured. One of the most noticeable features is the fine range of rooms on the attic floor level, all lighted from the internal court. By a novel construction of the roof, the space usually wasted has been utilised to the fullest extent, and rooms for draughtsmen and others have been provided.

The system of drainage is somewhat of a new departure in Government offices of this class, the whole of the piping, which is of iron, being in sight, so that any leakage can be at once detected. It was necessary to make provision against the effects of high tides and storms. Consequently, what may be described as four lines of defence have been laid—first, large automatic ball traps; second, sluice gates; third, a storm chamber beneath the Horse Guards Parade, the latter being sufficient to receive more than an inch of rainfall; and fourth, a sump at a lower level than the foundations.

Ample accommodation is provided throughout for the numerous departments. Overlooking the Horse Guards Parade is situate the First Lord's room, while facing the park, and overlooking the Horse Guards Parade, are the rooms for the various Naval Lords, Secretary's suite, and other principal officers. The cupola on the present new block will be duplicated at the south end of the old building, while in the centre of the connecting block still to be erected will be a fine dome. The connecting block is being planned on lines somewhat different from those in the first block. Therein will be imitated the "bank-parlour system," often advocated in the House of Commons, several of the rooms being of comparatively large proportions. This second block will house the extensive general library of the Admiralty. There will also be a subscription library, several committee-rooms, and ample provision for the caterer's department. The rooms for the latter purpose

will practically be isolated from the remainder of the building, and they will be self-contained, so that the catering may be done on the co-operative system.

These buildings have been erected from the designs of Messrs. Leeming & Leeming, of Westminster and Halifax.

PATENTS.

[This List of Patents is compiled specially for this Journal by Mr. G. H. Rayner, of the firm of Rayner & Co., Consulting Patent Agents, 37 Chancery Lane, London, W.C., from whom all particulars and information relating to Patents may be had gratuitously.]

APPLICATIONS FOR PATENTS.

- 24565. Frederick John Burrell, for "Improvements in sash-fasteners."
- 24648. Heinrich Hoopman, for "Improvements in roofing tiles."
- 24664. Harry Francis, for "Improvements in appliances for holding windows and preventing rattling."
- 24670. Robert Youngh Ardagh and Charles John Moss, for "Improvements in connecting paving blocks for making suspended roadways, footways, flooring, bridging, stairways and for other like purposes."
- 24705. Joseph Hazelhurst and Peter Jackson, for "Improvements in chimney-tops or ventilating terminals, or the like."
- 24750. Israel Cartwright, for "An improved weather shield or draught-preventer for doors."
- 24757. John Green, William Rowland Green and Herbert Haguf, for "Improvements in ventilators."
- 24987. William Whitely, jun., for "Improvements in self-closing appliances for doors, windows, gates and the like."
- 24994. Johann Scheck, for "Improvements in building stones and bricks."

TO INVENTORS.—Patents for Inventions, Trade-marks and Designs secured; every assistance given to inventors. Specialists in Building matters. Information free.—Messrs. RAYNER & CO., Patent Agents, 37 Chancery Lane, London, W.C.

WINTER, WARMTH AND COMFORT.

HEATING AND VENTILATING APPARATUS. GRUNDY'S SPECIALTY. PURE WARM AIR.

UPWARDS OF ONE THOUSAND TESTIMONIALS RECEIVED.

PURE WARM AIR AS SUPPLIED TO

Truro Cathedral; Londonderry Cathedral; Sherborne Abbey; Kilmore Cathedral; Stanley Cathedral, Falkland Islands; Cardiff Catholic Cathedral; the Queen's School Chapel, Eton; Cork Asylum; Leicester Asylum; and to upwards of three thousand Places of Worship; and a great number of Mansions, Houses, Hotels, Hospitals, Schools, Warehouses, Factories, Workhouses; Cork Law Courts, &c., &c.

84 Brook Street, Grosvenor Square, W.: December 8, 1893.

Sir WILLIAM BROADBENT encloses cheque for the "GRUNDY" HEATING APPARATUS supplied to his house, and is glad to say that it has proved very satisfactory for warming and ventilating as required. The principle of the apparatus is most excellent.

To Mr. Grundy.

PROFESSOR TYNDALL writes:—

Dear Sir,—My house being so well provided with grates and flues for the generation and distribution of pure warm air, I have been thus enabled to spend my winters in England instead of on a foreign shore.—Yours very truly,

JOHN TYNDALL.

Fever Hospital and House of Recovery, Cork Street, Dublin: October 26, 1894.

Dear Sir,—I have much pleasure in informing you that we have found your HEATING APPARATUS a great success in our new Epidemic Hospital, which consists of a two-storey building, each storey containing two large wards, a smaller isolation ward, and two nurses' rooms. It is easily managed, does not cost much for fuel, and the air entering is most pleasant, warm, and free from smell. It is with the full concurrence of the Managing Committee I give you this testimonial. Yours faithfully, JOHN MARSHALL DAY, Registrar and Resident Medical Officer.

THE

Architect and Contract Reporter.

NEW READING CASE.

To Librarians of the Public Libraries and Reading-rooms.—A new handsome Reading Case can be supplied at a nominal charge of 2s., by post 2s. 6d., on early application to the Publisher, 175 Strand, W.C.

SPECIAL NOTICE TO THE TRADE AND OTHERS.

[Extract from a lecture on Architects' Libraries by Professor T. Roger Smith, F.R.I.B.A., at University College, October 10, 1893.]

"Lastly, let me recommend the back volumes of the professional journals. In the course of years all sorts of architectural topics come up in the public press and before the professional societies, and if you hunt through the indexes of these publications when you are seeking for information which eludes you in books, you will often be rewarded."

There has been a considerable demand for the back numbers of *The Architect* during the last three or four months, which we have no doubt has arisen from the remarks made by Professor Roger Smith, as contained in the above quotation; but the consequence has been that our stock of back numbers is getting very low, and consequently, in future, the charge for back numbers of previous date to January 12, 1894, will be 6d. each.

A few of the back volumes may still be had, price 12s. each.

EDITORIAL NOTICES.

The authors of signed articles and papers read in public must necessarily be held responsible for their contents.

No communication can be inserted unless authenticated by the name and address of the writer—not in every case for publication, but as a guarantee of good faith.

Correspondents are requested as much as possible to make their communications brief. The space we can devote to Correspondence will not usually permit our inserting lengthy communications.

THE plans committee of Aberdeen Town Council have sanctioned plans of six large houses to be erected in Queen's Road South, the estimated cost being 10,000l. Plans of ten houses to be put up in Duthie Terrace were also passed, the cost of them being 5,000l.

TRADE NOTES.

WITH reference to the note last week on the new buildings to be known as the General Post Office North, the whole of the very handsome railing around which has been supplied by Messrs. Yates, Haywood & Co., of Rotherham and Upper Thames Street, London, E.C., we understand that the passenger lift in the main staircase, having a stroke of 62 feet, is a patent water-saving variable power lift made by Messrs. Easton, Anderson & Goolden, Limited, of 3 Whitehall Place, S.W., and Erith, who have also constructed three suspended lifts and two direct-acting goods lifts for that building. Similar lifts are being supplied by the above firm to the Royal Academy, Royal United Service Institution, the Commercial Union Assurance Company, Cornhill (two), Guardian Life Assurance (two), London and Midland Bank, Mr. J. Evitt Nash, Cadogan Square, S.W. (two); Mr. Bruce Clarke, M.D., Harley Street, W.; St. Pancras Vestry Electric Lighting Station, &c.; and their patent electric lifts to Messrs. Daw & Sons, Mr. McEwan, M.P., 16 Charles Street; the Eagle Insurance Company, Limited, Pall Mall, &c. They have also been instructed to provide the ten lifts and crane required for the new warehouses being erected for Messrs. Pawson & Leafs, Limited, St. Paul's Churchyard.

A SPECIAL exhibition of new designs and decorations for 1895 has been made by Messrs. F. Walton & Co., Limited, sole manufacturers of "Lincrusta-Walton," the Sunbury wall decoration.

WE hear that Messrs. William Godwin & Son, Lugwardine Works, near Hereford, encaustic and art tile manufacturers, have lately received orders for tiling the chancel and nave of St. Martin's Church, Hereford, and the chancel of Turner's Hill Church, Sussex; Hinton Church and Frocester Church, Gloucestershire. This firm particularly excel in the production of ecclesiastical designs and have taken great pains in reproducing ancient patterns, of which they have an admirable collection, and we have pleasure in stating that both in the excellence of manufacture and in the artistic quality their tiles are all that can be desired. We would like to mention that very fine pavements, the work of this firm, may be seen in St. David's Cathedral and Tewkesbury Abbey. Of the former, the late Dean, who took a great interest in the work, writes:—"Messrs. Godwin's tiles have been used extensively in restoring St. David's Cathedral. Messrs. Godwin were employed by Sir Gilbert Scott to copy the fifteenth-century tiles in the

presbytery and in the choir of the cathedral, and to reproduce them, which they have done most successfully. In fact, I am glad to be able to express my entire satisfaction both as regards the appearance and the wear of Messrs. Godwin's tiles."

MESSRS. GEORGE PRICE, LIMITED, Wolverhampton, write us in connection with their new bending machinery:—We have just completed our new hydraulic plant, and are now making all our safes with the top, bottom and sides bent solid at all corners out of a single steel plate from $\frac{1}{4}$ to 1 inch in thickness, according to the quality of the safe. We believe this machinery is the most powerful ever used in the safe trade, and there can be no doubt that the safes turned out by it are the most perfect ever introduced. We are also introducing new patterns in iron doors, and have put down plant specially for this branch of the trade, with which we hope to be able to take a large share of this work.

WE learn that the Incandescent Gas-Light Company, Limited, have received an order from the India Office to instal their system in all the departments there, this decision having been arrived at after a prolonged trial of a few burners.

WE hear that Messrs. E. H. Shorland & Brother, of Manchester, have just supplied some more of their patent Manchester stoves to the Clayton Hospital, Wakefield, those previously supplied having proved very satisfactory.

THE following, dated December 15, 1894, has been received by Messrs. George Price, Limited, from Mr. John Melior, of Manchester:—During the destructive fire at my warehouse or the 11th inst., two of your safes (one purchased from you thirty-five and the other twelve years ago) perfectly preserved the whole of their contents, consisting of books, deeds, papers, &c. The safe purchased from you thirty-five years ago is the one which successfully resisted an attack by burglars some time since.

A NEW illuminated Cambridge quarter clock has been fixed in the parish church, Monk Bretton, Barnsley, in memory of the late Mr. Thomas Marsden, by his nephew, Mr. James Marsden, of Sheffield, the whole having been made and erected by Messrs. Wm. Potts & Sons, of Leeds and Newcastle-on-Tyne.

PLANS have been prepared for the erection of a new public bath at Walsall, the cost of which is estimated at about 7,500*l*.

BUILDING AND BUILDERS.

At the meeting of the Golcar School Board the plans for proposed alterations and additions to the Knowl Board School and a proposed new infants' school and board-room adjoining were finally approved. The plans had already been approved by the Education Department. The schools, when completed, will provide accommodation for 407 children. It was also decided to advertise for tenders. Mr. J. Berry, 9 Queen Street, Huddersfield, is the architect.

THE Empire Theatre, Southend-on-Sea, has been destroyed by fire. Mr. F. Marlow, late of the Eastern Empire, Bow, purchased the property about a year ago, and spent a considerable sum in improving the building, which was insured for 4,000*l*.

THE sum of over 1,700*l*. has been received by Mr. W. Quarrier to build another cottage house in the national group of Orphan Homes of Scotland at Bridge of Weir, in memory of the late Mr. Ebenezer Dean.

THE death is announced of Mr. William Staple, builder, of Helston, in his sixty-fifth year.

SPEAKING of the church at Eccles-next-the-Sea, the *Norwich Mercury* says:—The old steeple had a rough time of it during the late gales. The sea has washed away large portions of sand, leaving the tower yet more isolated. At high tide the base has been submerged in 10 feet of water, the waves reaching at times half-way to the summit, and portions of the walls of the church adjoining the tower at the top of the arch being detached. Mr. G. Wilkinson, of the Castle Farm, with a view to its preservation, has caused the base of it to be cemented, especially those parts where the outer casing of faced flints has been removed. The beach has not been scoured so much as in some gales, but enough sand has been removed to allow some portions of the ruined nave and chancel to become visible.

THE County Clerk for Sutherland has received intimation that the Secretary for Scotland will recommend the Board of Trade to sanction the lengthening of the pier at Golspie, at present being constructed there, and in the event of the Board of Trade approving, the Treasury will be asked for 300*l*. of an additional grant.

THE Edinburgh Town Council have remitted to the Lord Provost's committee the question of cabling the tramway system of the city.

GILBERT WOOD & CO., 175 STRAND, LONDON, W.C.

THE Government have decided to erect a new fort at St. Anthony's Head, opposite Falmouth Harbour. It will be of a much more formidable character than the fort at Pendennis Castle, on the Falmouth side of the harbour, and contracts are already out for work involving an expenditure of 111,000*l*. Several acres of land have been marked off for the purpose. The construction of the new fort is expected to give employment to hundreds of men for a considerable period.

THE parish church of St. Columb Major, near Truro, was struck by lightning during the evening service. The tower was first struck, and the current travelled down the belfry and central aisle. The belfry was completely wrecked.

ELECTRICAL.

AT the meeting of the Manchester Society of Architects on Tuesday, the 8th inst, Mr. E. A. Claremont (F. H. Royce & Co., Limited) read a paper on the subject of electric lighting. He stated that the demand for electro motors would within the next few years in all probability increase enormously, owing to its having been lately demonstrated that in works where steam power is for driving purposes transmitted long distances and subdivided by the use of many small engines, considerable economy in coal can be effected, sometimes even to the extent of 50 per cent. By the use of electro motors not only is the great loss caused by condensation avoided, but the motors are so convenient to manipulate that they permit of the energy being absolutely cut off when necessary. The economy effected by such a system would be so great as in many instances to save the expenditure of the plant within a few years of purchasing.

THE Liverpool Corporation have under considered a proposal of a special committee that they should be authorised to try to arrange for the acquisition of the Liverpool Electric Supply Company's undertaking. The recommendation has been adopted.

THE electric-lighting committee of the Stafford Town Council having recommended that the tender of the Electric Storage Syndicate should be accepted for the construction of the accumulators at a cost of 822*l*.; also that one of 524*l*. 18*s*. from the Electric Construction Company (Wolverhampton) be accepted, the recommendation has been agreed to by the Council.

THE Aberdeen Municipal Buildings are to be lighted by electricity, and the tender of Messrs. New & Mayne, amounting to 200*l*., has been accepted. The Town Council also sanctioned the acceptance of the offer of Messrs. J. H. Holmes & Co., Newcastle-on-Tyne, for the supply of additional engines, dynamos, steam and exhaust pipes, &c., in connection with the electric-lighting station at Cotton Street. The cost of the new apparatus is 3,270*l*.

THE first of the Cantor Lectures at the Society of Arts will be delivered on Monday, the 14th inst, by Professor Silvanus P. Thompson, D.Sc., F.R.S., on the "Discovery of the Electric Arc Light, Early Experiments, the Physics of the Arc," &c.

AT the next meeting of the Walsall Town Council the following tenders will be submitted for acceptance for the carrying out of the electric-lighting scheme:—By Thomas Parker, Limited, Wolverhampton, for supplying plant (except mains) for the generating station, for the sum of 5,611*l*.; by the Callender Bitumen Telegraph and Waterproof Company, Limited, London, for supplying and laying down the electrical mains, for the sum of 4,000*l*.; and by Mr. H. Gough, Wolverhampton, for constructing a generating station at the Wolverhampton Street Gasworks, for the sum of 1,750*l*.

THE Surveyor of the Llanelly Local Board has just prepared a report upon the probable cost of electric light for the market in place of gas. He says that unless some of the tradesmen of the town also agree to go in for the new illuminant, a scheme for its introduction could not be carried out. Circulars have now been addressed to the principal tradesmen asking them whether they are prepared to adopt the change.

VARIETIES.

ON account of the success of the exhibition of artistic posters at the Royal Aquarium, Mr. Edward Bella, with the assistance of the honorary committee, has, by permission of the directors, increased it by about sixty additional posters, many of them by English artists. Examples are now shown by Sir James D. Linton, P.R.I., Chas. Green, R.I., Fredk. Barnard, Walter Crane, Linley Sambourne, Herbert Schmalz, Aubrey Beardsley, Mrs. Dearmer, A. Morrow, F. Simpson, Dudley Hardy and Professor Anning Bell. The famous original design for the poster of "The Woman in White," by the late Fredk. Walker, A.R.A., that has excited so much admiration in the foreign press, is still on view, and the numerous unpublished designs

for posters by English artists only prove that for originality and boldness our countrymen are beginning to show to advantage, even when contrasted with some of the brilliant colourists of foreign schools.

THE scheme for putting Sheffield in direct communication with the sea at Goole by means of wide deep canals is taking practical shape.

AN inquiry has been held by the Local Government Board, at the Solihull Workhouse, into an application made by the local authority for powers to borrow 1,000*l.* for works of sewage at Olton.

THE Japanese Government have decided to construct a new railway, 110 miles long, from Hiroshima to Shimonoseki, with one or two branches, and are prepared to receive tenders for material and locomotives. These latter are to be of the leading bogie type, about 45 tons weight in working order. The cost of the line will be about three million dollars.

THE Great Northern Railway Company are testing a novel method of warning the public at level crossings by means of a neatly contrived piece of mechanism. When an approaching train is within a certain distance of the crossing the engine in passing causes the mechanical device to be operated, thus giving an instantaneous ringing of a bell affixed at the crossing. The method is now in use on a portion of the Hatfield and Dunstable branch, and so far seems to be working satisfactorily.

AT the meeting of the Institution of Civil Engineers of Ireland—Mr. James Price, president, in the chair—the president, in opening the proceedings, thanked the members of the Institution for electing him their chairman for the ensuing year. Papers were read on "Damage to a Three-inch Main by Electric Discharge," by Mr. H. C. Moore, C.E., communicated by Mr. Charles P. Cotton (past president), and "Distinctive Features and Advantages of American Bridge Practice," by Edward Barrington.

It has been decided to erect a chancel to Oldwindsford Church, Stourbridge. The cost of the work has been estimated by Mr. Chatwin, architect, of Birmingham, at about 3,000*l.*

THE medical officer of health for Stockport, Dr. Porter, refers in a report just presented to the Corporation to the sewerage works now in progress and to the means adopted for sewer ventilation. The scheme now being carried out under the supervision of Mr. A. M. Fowler, M.I.C.E., at a cost of about 100,000*l.*, provides for five main intercepting sewers,

which are to be ventilated by openings in the carriage-way and by shafts on buildings, away from windows.

THE first number of the *Staffordshire Advertiser* was published on Saturday, January 3, 1795. A facsimile of that number has just been presented to the subscribers of that paper on occasion of the centenary. There are no allusions to architectural or building matters. We find, however, the following paragraph:—"It is said that the experiments for draining land, on the principles of a Warwickshire farmer, respecting which a committee of the Board of Agriculture, consisting of the Duke of Bedford, Sir Joseph Banks, Mr. Fordyce, &c., met at Woburn, are likely to succeed in a manner that will much promote that great means of improvement."

AT Bridgnorth an inquiry has been held by the Local Government Board relative to an application of the Town Council to borrow 5,000*l.* for the purpose of erecting dwellings for the working classes, under the Housing of the Working Classes Act 1890, and for approval of the appropriation to the object of certain corporate land and funds.

AT the meeting of the Cardiff School Board, the recommendation of the sites and buildings committee for the purchase of the two houses adjoining the higher grade school for 2,500*l.*, that they might be utilised for Board offices, the leasehold and reversion to be purchased, and a pupil teachers' school, gymnasium and workshops erected at the back of the house, was adopted. The plans were approved, subject to modification hereafter, and Messrs. Jones, Richards & Budgen were appointed architects.

THE North Berwick Town Council and Police Commissioners have resolved to proceed at once with a scheme of alterations and improvements on the existing drainage system of the burgh, at an estimated cost of 1,300*l.*

AT the meeting of the members of the West Riding County Council, the general asylums committee was given power to purchase, if they thought fit, land at Burley-in-Wharfedale, on which to erect an asylum for private patients.

THE committee of the Walsall Town Council recommend an application to the Local Government Board for power to borrow when necessary a further sum of 50,000*l.* for the purpose of the gas undertaking, the present borrowing powers of the Corporation being nearly exhausted, and to approve of the laying of an independent gas main from the Pleck Gasworks to the Wolverhampton Street Gasworks, at an estimated cost of 792*l.*

NOTES ON NOVELTIES.

WE are informed by Messrs. Marion & Co., Soho Square, that they have just issued a new form of hand camera, "The Persé." The use of celluloid films is largely on the increase, as for tourists it saves the weight and space of glass. The Persé film camera is designed to carry fifty to seventy sheets of the prepared celluloid film, of any make; and not only that, but the traveller who, having exhausted his stock of the correct size, yet having some of larger sizes, or even glass plates, may readily extemporise a new supply, which would be utterly impossible with the other forms. The few and simple mechanical operations required by the Persé are such that anyone with ordinary care can properly perform them; and the portability of the camera, from its light weight and small bulk, is such that it can be used anywhere. It is quite unnecessary for the operator to be acquainted with the chemical part of photography. The Persé is a well-seasoned mahogany case, covered with hard-grained black morocco, and having no other projections than those shown in illustration on the side—the finder being hinged so as to fold into a recess at the bottom, where it is held by a spring fastening. Inside it is fitted with light metal mechanism for holding before exposure and storing after exposure the thin sheets of celluloid film which carry the sensitive preparation. Behind each of these sensitive films is a "backing" sheet of a slightly different size. These are held by pressure springs in position for exposure against a series of catches operated from the outside by a lever, which, when raised, liberates a film, and on being lowered allows one of the backings to fall. This is automatically recorded by the visible index at the side. In the Persé any ordinary make of film can be used, which is an immense advantage over those cameras which require the edges to be specially notched, or in flimsy rolls. The Persé may be charged with one film at a time, or any number up to 70, and with-

drawn with equal ease in the same manner, or *en masse* as desired. If more than fifty are put in, then some must be removed from the receiver after exposure, for it will not hold more than fifty, but the top or reservoir part will take seventy. Letters showing on the outside indicate the inside conditions of certain parts. The Persé is fitted with an excellent rapid rectilinear lens with f.8 aperture and rotating stops. In front of this is a time and instantaneous shutter which always retains the same relative position to the lens. Both the lens and shutter are fixed on a "rising" and "cross" front. Focussing is done by moving an index lever over a graduated scale. After fixing the lens in the Persé the focus is tested for various measured distances from 6 feet to infinity, and the result obtained is marked on the scale referred to. By this means any object between 6 feet and infinity can be instantly focussed, which is impossible with lenses of fixed focus. The door at the front is hinged, and can be opened in a moment to alter the speed of shutter, diaphragms, or adjust the rising front. The lens aperture is covered with a square hinged lid which keeps out dust from the shutter and lens, and also gives the Persé a neater appearance. Sockets are sunk in the bottom and side of case to enable its being attached either vertically or horizontally by a screw to a tripod. A handbook on the Persé has been published by Messrs. Marion & Co., which gives very clearly full instructions on the use of the camera.

THE new window, which is the invention of Mr. Lanham, of Sawbridgeworth, Herts, presents some excellent features. In the first place it can be cleaned from the inside. The window is of swing form, the sash turning on a horizontal axis, and being capable of turning completely round, either face of the window can be situated at the inside. This complete reversal is a point of special importance. An automatic catch retains the sash in a closed position, and a further catch of special construction fixes it in any position, whether open or closed. This invention deserves consideration from architects and others.

THE plugs of washhand basins have been a great nuisance because they sometimes get mislaid, and they frequently fall into the basin and stop up the outlet, necessitating the user putting his hand into the soapy water to fish out the plug. The patent which we illustrate herewith gets over all this, and is very convenient in use as well. The engraving shows Winn's back-outlet "Washington," with patent chain, manufactured by Messrs. Charles Winn & Co., of Birmingham. It shows an

CARVED OAK AND ANTIQUE DEPARTMENT, No. 204 TOTTENHAM COURT ROAD.

Replica of an OLD ENGLISH Carved Oak Hall Press, 16th century, 5 feet wide, 7 feet 6 inches high.

arrangement by which the chain is passed through a suitable hole in the flat part of the lavatory and is weighted at the end, the effect being that so soon as the rubber plug is released from its socket the chain passes through the hole out of sight, and the rubber plug is held on the top of the slab, thus preventing the annoyance of picking it out of the basin, where it frequently

falls in the ordinary way, stopping the free discharge of the water. The particular shape of the basin, which is vertical at the back, thus providing the greatest depth where most required and thereby economising water is another advantage, while the user has more space under his elbows than can be obtained in the ordinary form. The outlet and overflow being recessed into the back, the plug and chain are entirely out of the way of the hands. When the lavatories are required complete with cocks there is an extremely neat pattern of screw-down valve for hot and cold water (registered), having handsome spoke top and complete with fly-nut and union for connection to lead pipe, with a full way plug and washer complete (with patent chain), at a very reasonable addition to the price of the lavatory.

Impervious Casements and Frames. — A thoroughly waterproof and universally applicable section, known as the Impervious No. A1, for metal casements and frames of all kinds, has been patented by Mr. Arthur W. Adams. The convenient and neat form and simplicity of detail of the section will at once recommend itself, while it gives strength and rigidity. This Impervious section is suitable alike for casements or windows opening on hinges or centres in any direction, or for fanlights, ventilators, hoppers, &c, while for meeting casements or doors without a centre mullion it is invaluable. In regard to the fixing, it is worth noting that this section will

accommodate jambs of stone, wood, &c, of any detail; the grooves or plugs usually prepared in stone jambs for fixing may be dispensed with, in which case a series of gaps is provided along one of the projecting ridges of the fixed frame, so that cement or other suitable fixing material previously applied to the stone rebate will flow through and form a key behind the section when it is pressed into its place. This will also make a draught-proof fixing. In the Impervious No. A1 section there are four surfaces of contact, the true fitting of each one being insured by using the same detail for the sash as the frame. The

members serve materially to strengthen and stiffen the window, a most important consideration. A condensed water channel which collects and diverts interior moisture is provided, and a groove for affording a good hold for the putty. The Impervious section makes a splendid sill or water bar for wood casements opening in or out, or for weatherproofing bad joints. These superior casements, which have been highly spoken of and used for the best work, are made of the best material and well finished by Mr. Robert Adams, No. 67 Newington Causeway, London, S.E. The prices are kept quite moderate, to enable these casements to be adopted everywhere.

SANITARY APPLIANCES.

WE recently paid a visit to the works of Mr. Milton Syer, of Rye Lane, Peckham, and a short account of a few of his excellent specialties will be of interest to our readers. The engravings No. 1 and No. 2 show the patent "Reliable" joint. This is a simple way of securing a reliable and effective joint without the rigidity of other methods, which are subject to breakage owing to settlement of the work or any slight strain. There is in the "Reliable" an

FIG. 1

FIG. 2

amount of elasticity which gives a certain movement or play, thus counteracting any effect of settlement or strain, and unbreakable, and forming a perfect water and gas-tight joint. In

fixing the joint the *modus operandi* appears to be that one iron ring is passed over the trap, then the indiarubber ring is sprung on, and lastly a second iron ring is passed over the lead soil pipe, which is tafted so as to form a shoulder, the bolts are put in, and the whole screwed up tight together and the work is complete. Among other appliances manufactured at the Hanover Works are several kinds of cisterns, all excellent. Among them is the "Peckham" syphon cistern, some 80,000 of which have already been sold, and which received a medal at the Inventions Exhibition. It has great flushing power, and flushes well at a low head of water. The flush is certain whether the lever is held or not. Valves—excepting ball valve—rubbers, washers, &c., are entirely dispensed with, avoiding any chance of getting out of order. The patent "Hanover" is an improved syphon cistern, meeting the requirements of the water companies as a perfect water-waste preventer, and passed by the Kent Water Company. The inner flush pipe stands over the water-line and overflow. The syphon cannot be started unless the lever is pulled and allowed to fall again. The handle, if held down,

FIG. 3.

FIG. 4.

does not allow water to pass. It is claimed as one of the simplest and most efficient cisterns in the market. There are no seatings or valves, or anything to get out of order; also, the syphon is easy of access. The "Reliable" or electric flushing cistern is very simply put in action by pressing a button, for which no extra battery is required if electric bells are fitted in the building. Levers, chains, wires, &c., are dispensed with. There are no moving parts, and the action is perfectly silent. The "Peckham" is an automatic flushing tank for latrines, drains, urinals, &c., eminently adapted for public purposes. There is also the "Peckham" urinal flushing cistern,

automatic in action. As a self-flushing cistern it is very excellent, and simply constructed with absence of all mechanism to get out of order. The flush can only be set going by use of the urinal, so it perfectly prevents all waste of water. The "Universal" is another excellent appliance as a syphon cistern. The engravings, Nos. 3 to 6 inclusive, show the "Reliable" drain or pipe stopper. All screwing and expanding of rubber rings is dispensed with. This plug pressed into the pipe becomes a fixture and perfect tight seal at once without any further attention; the greater the pressure exerted on it the tighter it will hold. To release it

FIG. 5.

FIG. 6.

the capstan handle A must be unscrewed and withdrawn, when, after the water has been allowed to escape, then the plate B with rubber flange C can be withdrawn and the handle replaced, leaving it ready for the next test. Can be made in any size required to order. This plug will be found very useful for testing cast-iron pipes and stopping gas mains under repair. If desired, the capstan handle can be supplied with a screw-cap so that a tube can be attached to it. No. 3 shows an elevation of the "Reliable" plug, No. 4 represents the plug inside of drain-pipe, No. 5 shows the plug with capstan handle removed, No. 6 is the section of the plug inside a drain-pipe. A is capstan handle, B the double-flanged plate carrying the rubber flange C.

THE resuscitation of the Cheltenham Spa is proposed, and the borough surveyor has prepared a sketch-plan of a small pump-room and suitable adjuncts at the north corner of the Montpellier Gardens, the cost of which he estimates at about 3,500/.

PHILÆ AND THE LOW-LEVEL DAM.

A CORRESPONDENT of the *Times* in a communication to that journal writes:—

Sentiment prevails over utility so rarely in the present age that its triumph in the matter of Philæ calls for more than passing remark. The lay protests of artists, archæologists and amateurs of things beautiful have won the day, and the immediate construction of a storage basin, sufficient for the whole of Egypt, is renounced definitely out of regard to the monuments it would submerge. The final proposal of the Ministry of Public Works has reference only to a low-level dam to be constructed at the Assouan Cataract, with a view to holding up water sufficient for Middle Egypt in a bad year, and for part of Lower Egypt also in a season of high flood. A pious hope is expressed that this may be supplemented ere long by a second dam in the Northern Soudan; but nothing is contemplated definitely beyond the Assouan barrage, which will be 26 feet lower than the high-level one proposed originally, and, it is said, so constructed that all possibility of its being heightened at a subsequent period will be precluded.

The triumph of sentiment is the more remarkable since certain of the protests put forward last spring and summer on its behalf were weakened materially by insufficient knowledge on the part of the protesters. Those, for example, who pressed the claims of a dam at Kalabsheh against one at Assouan, on the ground of the very slight excess of its cost, spoke in ignorance that the International Commission of March last had declared the difference to be nearly one million sterling. And we learn now that the technical advisers of the Government insist that one at least of the storage reservoirs must be removed from the districts to be benefited not further than the cataract, in view of the immense waste of water by evaporation and infiltration which must be reckoned with were the distance greater. Wisely, however, the spirit of the protests has been regarded in Egypt rather than their expression. The technical advisers have changed their policy, perhaps with no great reluctance, for it is an open secret that many of those most concerned with the reservoir schemes were neither Philistine at heart nor anxious to put their hands and names to a deed which many would be found in all ages to regret.

The outcome is, of course, a compromise, and the out-and-out advocates of utility and sentiment are called upon to make mutual concessions. Certain details are undetermined as yet, and will be referred to expert opinion, but enough is settled for

30 & 31 NEWGATE ST., LONDON, E.C.

it to be possible to judge how the "sentimental" outlook now stands. Two chief points are established: the Temple of Isis is to be touched in no part by the waters, and all the Nubian temples above Philæ will be well above the highest level of the new lake. The "sentimental" question, so far as one remains, concerns only the lower-lying buildings on the Philæ Island, and its general aspect (for no one would put forward the *graffiti* on isolated rocks as monuments of sufficient importance to be taken seriously into account). It now appears that, for rather less than two months of every year (March and April), the Temple of Isis will stand reflected in the surface of a lake, washing to within a very few feet of the base of its walls. To the south the colonnade will be dry, except, perhaps, at its extreme end, where the earliest of the Philæ builders, the magician Nectambo, erected a shrine to Hathor. Here a thin film of water will soak among the fallen blocks and over the top of the quay wall. North of the temple, most of the labyrinth of brick constructions will be submerged, and nothing will show conspicuously on the eastern side except the shafts, abaci and architraves of Pharaoh's Bed submerged nearly to the top of the intercolumnar screen. The whole northern and eastern quay will be deep under the surface, but at the south-eastern corner the rock rises and will preserve a group of brick buildings.

The full effect of the submersion of what is to be submerged cannot be estimated until submersion has taken place many times. There will remain, of course, every spring, a coating of slime, but it will be as easy to wash this away at Philæ as now at Luxor and Karnak. The brick structures, it is to be feared, will have vanished utterly wherever reached by the flood. Their value is rather scientific than artistic, and will be estimated very variously. What, however, of important stone structures like the quays and Pharaoh's Bed? On the safety of the south-western quay wall depends that of the western colonnade; it is rickety at present, but would be underpinned, clamped and strengthened in every possible way before the basin was filled for the first time. "Pharaoh's Bed" is too solid to be endangered by the mechanical action of the water; but, like the other structures, it may suffer seriously from chemical action. There would not be in it or in any other building paintings of much merit within reach of the highest level, or even of the damp, which, as at Karnak, would creep up some feet higher than the surface of the lake; but, unfortunately, Nile salts can disintegrate matter more solid than pigments. Their evil work, slow but sure, can be seen at Karnak, in the eroded bases of pillars and scaling of all surfaces below the flood mark. The Philæ

water would doubtless be less impregnated, being stiller, deeper and drawn off granite, and would do its work of destruction even more slowly than at Karnak; much, too, might be effected by judicious washing after the flood or coating the exposed surface with some transparent composition before the basin was filled.

The danger from salts has prompted an official suggestion that watertight walls should be built round the monuments lying below high water mark, or one such wall round the whole island. In this case prevention would seem worse than cure—worse even than disease. The lake will endure for a season, the wall always. The chief glory of the island, its general effect from the further bank of the Nile, would have been ruined for ever. Philæ would be no longer the Philæ of indelible memories of sunlit columns and towers set in a frame of leaning palms, dark waters and fantastic crags; it will have sunk to a dreary museum of antiquities. In any case, if no wall be built, a few more generations will be able to enjoy as of old one of the most matchless views in the world; then, if it must be, let the buildings crumble. The men of science will long ere this have unlocked all secrets and published all details. Why preserve for their sake what they will care little for by the destruction of all that made it worth preserving for the rest of the world?

In all this matter of the preservation of Philæ science has been considered too much and sentiment too little. The out-and-out archaeologist has really very little interest in the question. When he has planned, copied, drawn and photographed a building he wishes to pull it to pieces and dig in its foundations; like a botanist, he learns more by dissection and uprooting than by conservation. He would have gained, rather than lost, by the once proposed transportation of the Temple of Isis to the island of Bigeh; he will gain now by the justification afforded him for digging out the brick constructions down to the old level of the island more than he will lose by their eventual solution in the flood waters. The "sentimentalist" it is—he whose æsthetic and religious senses are developed strongly—who has the most real interest in the preservation of the monuments of Philæ, together with the general character of their natural setting. If no wall be built he will see the island still in December and January much as of old, and in February as it appears now at High Nile. Science can surely minimise the destructive power of the salts; at the worst, from time to time the rotting stones of the lower courses can be replaced by new, and even sculptures reproduced, as is done again and again on our own Mediæval monuments. The Ministry of Public Works professes its willingness to do

THE MOST PERFECT AND RELIABLE SYSTEM OF

VENTILATION AND HEATING FOR

SCHOOLS, AND EVERY CLASS OF BUILDING.

The air of Class-rooms renewed every six minutes in all weathers positively and without draughts, no foul air anywhere; for a school of 1,000 68 tons weight of air impelled into it every hour. All buildings ventilated and warmed mechanically. No failures nor breakdowns. Estimates on Shortest Notice. Low Working Expenses.

all that is humanly possible; it is to be hoped that they will make provision for the up-keep of Philæ as well as for its present consolidation. If that be done it seems that archaeology and sentiment may be satisfied under a scheme which spares entirely the Isis Temple and colonnade and condemns to absolute destruction only the brick constructions, whose value, being wholly scientific, could be realised in full before their disappearance. In fact, the proposal of the Ministry includes so thorough a preliminary survey and exploration of the island that science proper will be able only to be grateful.

The further project of a survey of Nubia, announced lately, will result also in an incalculable gain to archaeological science, since exploration on all the ancient sites is put forward as an integral part of the scheme. It is devoutly to be wished that no *odium archaeologicum* may prevent all the best Egyptologists and explorers from responding to the generous invitation of the Government when it is formally made. But this scheme and the Philæ question are things wholly apart; the preservation of the monuments on the island is less the interest of archaeology than of sentiment; and the character of Philæ is so unique that it cannot be classed with any number of mere relics of antiquity. If its value is sufficient in itself to outweigh all the claims of present Egypt, neither would it be lessened nor the claims increased by the introduction into the balance of the Nubian temples. In connection with this and future schemes of water storage, a Nubian survey has become imperatively necessary, and its prosecution affords a singular opportunity for archaeological exploration *pari passu*; it is much to the credit of the Ministry of Public Works that it has recognised this fact so promptly and made so munificent an offer. Under the original scheme this proposition might have passed for a bribe to science; in view of the modified proposal it is a piece of laudable generosity.

IRISH HANDICRAFTS.

In the course of a paper in the *New Review*, the Earl of Mayo writes *à propos* of the forthcoming exhibition:—

A great deal of cabinet-maker's work is done in Dublin; in fact, I may say the trade flourishes, but the curse of Chippendale is over it all, or rather Chippendale, with extra Liffey Street inlaying. One's heart sinks when one sees year after year the same patterns produced and reproduced. Yet in

many cases the work is excellent and the carving good. One asks why this continual iteration, and one is told the public will have it; it is the fashion. I do not object to an adaptation of Chippendale, but I do object to Chippendale redecored. I have seen a beautiful piece of modern carving in Liffey Street, and have also seen small tables well and strongly made, adapted, it is true, from an old design. I have also seen a screen, with figures inlaid in the top of the panel, which showed a certain amount of originality. The secret of all this want of original design lies in the fact that designers of every sort are scarce in Ireland. If our country produces a good one he goes to England, as he would starve here.

Yet we have artists and amateurs who are able to design. I appeal to them to make a few original and simple designs for chairs, cabinets, and small tables. I am sure my old friends in and near Liffey Street will take pleasure in carrying out these designs. I hope the trade will not be offended by these remarks. I wish, in a humble way, to suggest the need for a large change. The Dublin cabinet-makers produce excellent work, which commands good prices, but their work is lacking in originality. People with taste can help them. Some do; I wish more would.

The next item on our schedule is cast-iron. One's thoughts are here instantly associated with kitchen ranges and sewer gratings. There are many foundries in Dublin, and although the possibility of artistic work in cast-iron seems small, let me point out that firebacks of bold design, strong, simple, effective railings and gates, and even fire-dogs can be produced in cast-iron. An exhibition might be overwhelmed with productions of cast-iron; but I trust my suggestions here will produce something worthy of the Dublin foundries.

Embossed leather I dismiss with these words, in this country it is entirely amateurs' work. There is just one gentleman in Dublin who is an adept in the craft. Germany is the country where this work is produced in perfection.

Next comes embroidery, lay and ecclesiastical, on silk, linen, or any other material. Here we are more at home, as Ireland produces some fine embroidery. Let me instance the ecclesiastical embroidery done in the Convent of Poor Clares, Kenmare, and especially their adoption of old Celtic designs for modern needlework. There is a school of art needlework in Dublin (Clare Street), which does good work, and the school is making money; also I may mention a centre of needleworkers at Strabane, celebrated for white embroidery on linen. In this, as in other arts and crafts in Ireland, a lack of good

"OPTIMUS" MAGIC LANTERNS SUITED FOR DRAWING ROOM AND LECTURE HALL.

Limelight may be adapted without alteration at an extra cost of 10s.

Each Magic Lantern is efficient for exhibitions. The Lens gives crisp definition, being a superior Achromatic Photographic Combination with rack and pinion. It is fitted to a telescopic lengthening tube, so gaining increased focal accommodation. The Condenser is composed of two plano-convex lens of 4 inches diameter. The refracting lamp has 3 wicks, yielding a brilliantly illuminated picture. Each is complete in box. Pairs for dissolving arranged in one Box at same prices. Lever Disolver, 8s. 9d.

designers is felt, especially in those conventional designs so suitable for hangings and curtains, which are seen in their best form on old Italian embroideries. One becomes a little tired of the shamrock—as an emblem excellent, but combined in a design decidedly wearisome. I feel that at our exhibition we shall have an excellent and brave show of embroideries of all kinds.

Next is engraving, lithography, and the various processes for book illustration. Here the workman is in touch with the artist, as wood-engraving gives every opportunity for the best work. There is one wood-engraver I know of in Dublin. As for the other processes, we shall expect a fine exhibit of this from Marcus Ward, of Belfast.

Zincotype work is well done in Dublin. Here again the connection of art with industry is observable; the better the drawing the better will the process do justice to it. In gesso, stucco and sgraffito work, at present only stucco work is done in Dublin. I am promised good designs, and one of our Dublin firms have said they will carry out these designs. The schools of art throughout Ireland should give us some stucco work, either finished or in design.

We have next gold and silversmiths' work. Here visions of old Irish plate rise up, perhaps to taunt one, epergnes, cups, and the rest, all beautiful, graceful and of excellent finish. Is there, then, no good plate made in Ireland? Yes; but the good and defunct Queen Anne must lend the style to our modern silversmiths. In plate she is the fashion, and so our silver workers go on copying. If an original design is produced it is over-decorated. Some of the presentation pieces of plate one sees in the shop windows in Dublin add a new terror to the recipients' attempts at making a speech on being presented with them. The workmanship is excellent, well finished and well carried out, but the same article can be seen in the London shop windows. When remonstrated with the maker will say, "People will have their money's worth. If we do not put in plenty of chasing they think they are not getting full value."

Instead of centre-pieces, football cups, and bicycle racing cups, I hope we may see at our exhibition some useful pieces of plate. They can be made, and made artistically—salt-cellars, coffee-pots, tea-pots, sugar bowls of simple design, one or two not over-elaborated epergnes, a good plateau, and a well-designed racing cup. I am perfectly certain that these, if not exhibiting vulgarity in detail, would be sold the first day the exhibition opened.

Hammered Ironwork.—There is no fear of a want of good

exhibits in this craft. There are two excellent workers in hammered iron in Dublin. I need only mention that the gates of the courtyard of the Science and Art Buildings were made in Dublin, and at a very moderate cost. In fact, we may feel proud of this craft as carried out in our capital.

Lace-Making.—Irish lace is known all over the world, and of late years has been commanding good prices, owing largely to the better designs introduced into this art by the efforts of Mr. Alan Cole, of the South Kensington Museum, who was sent over by the Treasury to visit the different centres, and to criticise and advise. He was equipped with examples of the finest old lace from South Kensington. This good work was continued by Mr. James Brenan, of the Metropolitan School of Art, Dublin. The Irish Industries Association are at present introducing new designs, especially in Carrickmacross laces. In this exhibit, which is sure to be excellent, will be seen the effect of good design, without which the craftsman may toil in vain.

Poplin.—Irish poplins bring visions of beauty adorned with richest grace of drapery. There are many poplins now made in Ireland with effective designs, which we trust will be forthcoming at our exhibition. Poplin has lately been made lighter, so as to drape in more graceful folds.

Porcelain and pottery come next on our list. As for the former, Belleek produces good china; but here, again, good designs are wanting. Those shell-like tea cups are no doubt delicate and almost pretty, but they are not useful or artistic. The Belleek glaze has a wonderful lustre, and would be effective if applied to designs and articles to which it is suitable. In the Dublin shop windows one perhaps only sees the plainer, merely pretty, products of Belleek. I know of two pieces in our museum which are artistic and worthy of a place in any exhibition as examples of ceramic art. I trust we may see some more in 1895.

Printing comes next. Artistic printing, in the true sense of the word, is not produced in Dublin. Perhaps one might often call what takes its place fantastical printing. The printing done in Dublin during the last century by Grierson was excellent. Good plain printing can be done in Dublin, and is done. A defect of Dublin printing, however, is that the types are of a very thin nature, and therefore will not take the ink properly. Very often the ink might be better. Like everything else, if you give a little time and attention to the matter, you can get good work. Choose a good bold type, and see that the spacing is properly arranged. A good paper is a great help to good

printing. We shall have a good exhibit of printing, but it will not be modern artistic work.

Repoussé Work.—This is entirely in the hands of amateurs. There is a school of metal work in co. Tyrone.

Seal-Cutting.—One is surprised to find that this craft is excellently represented in Dublin. I know myself of one good seal-cutter, and have no doubt our exhibition will produce more.

Wall-Paper Designs.—Here we have an opportunity for any young designer to make himself or herself known. In fact this is one of the objects of the forthcoming exhibition. I can assure anyone exhibiting good and original designs that it will not be long before some large firm seek the designer out and secure his services. Good designers are scarce. It may be an encouragement to say that one of the best, if not the best designer in the United Kingdom, is an Irishman, and head of the City and Guilds School, London.

Wood-Carving.—In this craft there are several schools in Ireland. I have not seen much of the work, but what I have seen shows a tendency to over-elaboration. There is one distinct feature of Irish wood-carving—it is bold and rough; perhaps a little too rough. In this, also, good design is wanting; if a good design is secured let the carver carry it out and not try to improve on it. Several Irish ladies foster and take the greatest interest in schools of wood-carving. Irish boys are apt pupils and take most kindly to this craft.

I hope those who read this article will not think I have been too severe on some of our crafts. I write to draw attention to the fact that good work can be done in Ireland. A beginning has, at any rate, been made; fresh ground has been broken, and we have here a work in which all parties in our party-loving country can join and help one another. Arts and crafts may be the means of leading us to a peaceful and friendly understanding of one another.

At the meeting of the Mersey Docks Board a scheme was submitted for the construction at the Pierhead of a railway station in connection with the North-Western line, as well as for lengthening the Prince's landing-stage and for additional dredging. The improvements, estimated to cost 36,800*l.*, have been suggested with the object of facilitating the Atlantic passenger traffic.

A YEAR'S BUILDING IN BIRMINGHAM.

MR. F. W. LLOYD, building surveyor, has forwarded us his annual report of new buildings, &c., for which plans were approved during the year 1894, along with a comparative statement of the three previous years. The total last year was 2,540; in 1893, 2,294; in 1892, 2,151; and in 1891, 1,541. These figures are made up as follows:—

	Houses and Shops.	Business Premises.	Warehouse and Shopping.	Miscellaneous.	Alterations and Additions.	Churches.	Chapels.	Schools.
1894	1,790	30	117	353	242	1	4	3
1893	1,058	26	149	291	163	2	3	3
1892	1,491	22	199	230	203	1	2	3
1891	966	36	183	214	139	0	0	3

As will be seen by the foregoing table one church has been erected, viz. St. Patrick's R.C., which is situate at Dudley Road and is in lieu of the temporary iron mission chapel. The following are the chapels:—Baptist, Arthur Road, Salliey; Working Men's, Lodge Road; Gospel Mission Hall, Ladypool Road; Christian Meeting Room, Mary Street, Balsall Heath. Amongst the miscellaneous buildings are included a temporary iron mission room, Camden Street, and another in Musgrave Road (Church of England). Other miscellaneous buildings are the City Meat Market, Bradford Street and Cheapside; extension of Church of England Girls' Friendly Society's premises, Barwick Street; extension of Eye Hospital, Edmund Street; Heath Green Road Sunday School; extension of Villiers Street School and mission room, and extension of Washwood Heath Church; additions to St. George's Mission Room, Smith Street; New Mission Room, Farm Street; and Mission Room, Norton Street, Balsall Heath. The new schools are:—Baptist, Arthur Road, Salliey; Board Schools, City Road; and Baptist Schools, Harborne. Additions to schools are:—Lavatories, Dixon Road Board Schools; classrooms, Foundry Road Board Schools, St. James's Schools, Parish Schools, Ampton Road; classrooms, Board School, Montgomery Street; Oratory Schools, Edgbaston; St. Chad's Cathedral School, Shadwell Street and Loveday Street; St. Peter's R.C. Schools, Broad Street, Wesleyan Schools, St. Martin's Street. Notices have been forwarded to property

AUSTIN'S

NEW IMPERIAL PATENT

SUPERFINE FLAX LINE.

The above article is now being manufactured and sold in large quantities for Greenhouse Sashes, Public-house Shutters and other heavy work. The Manufacturers would recommend it for its strength, and the large amount of wear in it, on account of its peculiar manufacture.

AUSTIN'S IMPERIAL PATENT FLAX SASH AND BLIND LINES (two Prize Medals awarded). The Manufacturers of the above articles particularly wish to draw the attention of the trade to their Imperial Patent Flax Sash Lines, of which they are now making six qualities, all of which they can strongly recommend, as they have given unqualified satisfaction to the trade for now over One Hundred Years, and the Proprietors continue to give their personal attention to the manufacture of these goods. They also invite the particular attention of the trade to their IMPERIAL PATENT BLIND LINES, which are very superior to anything yet offered. They can be obtained of all Rope-makers, Ironmongers, Merchants, Factors and Wholesale Houses in town and country.

N.B.—Please note that all our goods, as advertised above, are labelled, either inside or outside with our Trade Mark "The Anchor."

READING CASES.

A NEW well-made Reading Case for "The Architect" can be supplied on application to the Publisher, the charge for which is 2s. 6d.

owners and others in reference to dangerous buildings, &c., to the number of 740, and 247 factories have been visited re exits, &c., under the Factory and Workshops Act 1891, 223 of which have been dealt with in accordance with the requirements of the Act. Forty-five square yards of ground have been given up by property owners and others setting back projections, &c.

THE BY-LAWS IN WIMBLEDON.

In a letter to the *Times* Mr. T. G. Jackson, A.R.A., writes:—

Among other duties, the new district councils will inherit from their predecessors the administration of the Building Act. I venture to suggest that advantage be taken of this new departure to make a general inquiry into the rules by which their procedure will be governed, to revise them where needful, and, further, to provide some machinery for securing that the by-laws shall be fairly and justly enforced.

For instance, in this town there is a by-law prescribing a certain amount of open space behind every new building. Notwithstanding this, a local builder has intruded a large building into a confined backyard to the danger and annoyance of his neighbours, and in defiance of the conditions of open space.

Remonstrance with him only produced a threat to raise the offending building a storey higher.

A remonstrance addressed to the Local Board elicited at the end of a month the astounding declaration that, as the new building adjoined an old one, it was not a new building at all, and therefore was exempt from the by-laws.

It appears, therefore, that anybody in Wimbledon possessing an old cottage may add a mansion to it without any interference on the part of the local authority. I am informed by its officials that they could not prevent him from building his addition of wood and covering it with thatch in the midst of a thickly-crowded neighbourhood, nor make him build the walls of sufficient thickness for strength, or frame the floors and roofs of timbers stout enough for safety. Nor is there anything to prevent him from covering his site with building, leaving no air-space for himself and too little for his neighbours.

I venture to think the Local Board and its officers have wrongly understood their duties. The Metropolitan Building Act lays down the rule that every addition to an old building shall be treated as a new one, and there is nothing in the Wimbledon by-laws to justify this exemption. But the point

to which I wish to draw public attention through your columns is that if the Board is wrong, as I believe, there exists no machinery for making it do right. An appeal to the Local Government Board, which was delivered by hand at their office a month ago, has not yet been honoured by the usual official acknowledgment.

In this defect of any ready method of appeal I venture to think there is something that needs remedy. The parish councils may be an admirable device theoretically for the protection of the inhabitants; but one cannot help asking *Quis custodiet ipsos custodes?*

The reply of the Clerk to the Local Board is as follows:—

The Local Board of Wimbledon, which is about to become a district council, has, by virtue of the Public Health Acts and of by-laws made under those Acts and sanctioned by the Local Government Board, a certain control over "new buildings," and Mr. Jackson is astounded to hear that this control does not extend to additions to old buildings.

Mr. Jackson, as I understand, contends that an addition to an old building is, in fact, a new building. But any one connected with local government law knows very well that this is not so. The leading authority on the subject, if authority be needed, is "Shiel v. the Mayor of Sunderland," decided more than thirty years ago by Lord Chief Baron Pollock and Barons Martin and Bramwell, which shows that very extensive work may be done by way of addition to old buildings without any control by the local authority. Since then other cases of the kind have come before the Courts, the question usually being whether the work in dispute was a new building or an addition to an old building, and this is held to be a question not of law, but of fact, to be decided upon a consideration of all the circumstances of the case. Nobody, so far as I know (except Mr. Jackson), has ventured to contend that an addition to an old building is a new building. His reference to the Metropolitan Building Act is against his own view rather than in favour of it, since it shows that where the Legislature intends to give control over additions it gives it in express terms.

Mr. Jackson's suggestion that if additions are not subject to the by-laws anybody possessing an old cottage may add a mansion to it without interference by the local authority is, I think, fallacious, because the Court would probably hold that the mansion was not an addition in the proper sense of the word.

I need not discuss the question whether it is desirable that urban authorities should have control over additions to old

buildings. Personally, I should agree with Mr. Jackson that it is; but my only object in troubling you is to show that in the present state of the law urban authorities have no such control, and that the officials of the Wimbledon Local Board do not (as Mr. Jackson suggests they do) wrongly understand their duties in the matter.

Mr. Jackson, in reply, says:—The letter of the clerk to the Wimbledon Local Board reaffirms the statement that any owner of an old building at Wimbledon may make additions to it of insecure construction, combustible materials, such as wood or thatch, with insufficient air space indoors, and none at all of its own out of doors if he pleases to cover the whole of his site. Contiguous owners whose light and air and safety are compromised need not look to the Board for protection, as he says that body has no power of interfering.

I find it difficult to reconcile this with the fact that the building to which I referred in my former letter was submitted to the approval of the Board in the way usual with new buildings. The plans were deposited and passed, subject to certain alterations in thickness of walls, and copies of them were retained and filed by the surveyor. The building has, in fact, been treated as a new one, and has passed the ordeal of the Board, although it violates the by-laws with regard to the retention of open space.

There is another opening, according to the showing of the clerk to the Wimbledon Board, in which the Board can intervene. He says my suggestion that anybody possessing an old cottage can add a mansion to it without obeying the by-laws is fallacious, because that would not be regarded as an addition in the proper sense of the word. By what rule, then, does the Board decide when an addition ceases to be an addition and becomes a new building? Is it an addition so long as it remains less than the old building, and, if so, how much less? May it be as large? May it be larger, and, if so, how much larger? Here is obviously room for great latitude of interpretation, which ought not to be left to a body such as local boards are, and with practically no appeal from their judgment. For most men will submit to a substantial injustice rather than attempt to right themselves in a court of law.

Practically it seems to me that different local boards enforce their by-laws pretty much according to their different ideas of interpretation. Since my letter appeared in print a correspondent tells me of one rural board, at all events, which treats all additions as new buildings, just as they are treated under the Metropolitan Building Act. It is not to be desired

that the by-laws should be identical in all places; that would be a misfortune; but it is surely time that all places should be agreed as to the cases in which the local by-laws shall be enforced. The case would be met if Section 209 of the Metropolitan Building Act were extended to all places where the Public Health Acts are in operation.

There ought also, I repeat, to be some easy and inexpensive mode of appeal to which those who think their local board has decided wrongly might resort.

BUILDING IN EDINBURGH.

THE year just closed has been an active one in the building trade of Edinburgh. Taking the returns of the Dean of Guild Court, we find, says the *Glasgow Herald*, that during the twelve months ended in September the number of warrants granted was 633, a figure far in excess of any in recent years. It is true that 186 of these were for minor alterations and improvements, but even these count for something when, as was the case, the demand for larger classes of work was considerably over the average. According to Dean of Guild Miller, the warrants for house property granted authorised the construction of 72 first-class houses and villa residences and 753 tenement dwellings. Of this latter number, 224 were two-roomed houses, 284 houses of three rooms, and the remainder dwellings of four rooms and upwards. There is reason for belief, too, that notwithstanding this activity in providing for the housing of a rapidly-growing population, public requirements have not yet been fully met. According to Mr. Dowell's annual report on the state of the Edinburgh property market, the proportion of unlet property to the city rental, 2.45 per cent, is the lowest on record. Builders may, therefore, be expected to do as well in the incoming year as in the past, so far at least as dwelling accommodation is concerned. Many important works, however, on a more ambitious scale, have either been completed during the year or are rapidly nearing completion. One of these is the hall adjoining the new university buildings, which is at once an ornament to the city and a magnificent monument to the wisdom and liberality of Mr. M'Ewan, M.P. Thanks to the City Improvement Scheme, the old tenements which confronted the new hall and entirely hid from view the respectable edifice of the Students' Union have been removed, and a visitor to the city can now view both buildings without the necessity for odious comparisons being forced upon him. The open space

created by the scheme has not yet been utilised, but the propriety of placing on it a statue of one or other of the city's benefactors has been suggested. Another building which only needs internal fittings to complete it is the National Observatory on Blackford Hill. Standing on the ridge of the hill's eastern slope, the observatory is a prominent feature in the landscape, while for the astronomer's purpose its situation contrasts most favourably with that occupied so long on the Calton Hill. Other buildings that have also left the contractors' hands are the New Craig House Asylum for the Insane—a large edifice in the French Renaissance style which stands at the western extremity of the city—and the Morningside Free Church, a handsome building which has been built almost opposite its smaller predecessor, to meet the wants of the Free Church community in one of the most rapidly increasing portions of the city. In Princes Street the new structure which Messrs. Jenner have reared on the ruins of the old buildings destroyed by the great fire two years ago will not long remain unfinished. A few yards away Messrs. Cranston & Elliot, who have surrendered their present premises to the necessities of the North British Railway Company, are reconstructing the Edinburgh Hotel, and it may be hoped that, like Messrs. Jenner, they will add another notable feature to the amenity of the "finest street in Europe." The Roman Catholic community have begun a fine Gothic church in Slateford Road, and it will not be long before the reconstruction and extension of the pro-Cathedral in Broughton Street will be undertaken. The School Board promises to have one or two important works on hand during the present year; but one which is now in the builders' hands, and has already reached an advanced stage, is the school at Montpelier, one of the largest, and in its equipments perhaps the finest, for which the ratepayers have had to find the money. Another school for the St. Cuthbert and Dean Board has been erected in the Murrayfield and Coltbridge district. Of a different class is the work which has been going on for some time at the Haymarket Station, while the North British Railway Company are also providing for the convenience of travellers by erecting a new station at Broughton Road. The reconstruction of the North Bridge and the proposed re-erection of the Waverley Bridge are not undertakings which can greatly benefit builders, but they will at any rate provide some work for masons and members of one or two of the allied trades. House extension has taken place in the south, west, and north-west districts of the city. Little has been done in the Newington suburb, but, as in previous years, a good deal of feuing has

gone on in Morningside. The easy access which golfers have to the Braid Hills courses makes this suburb one of the most popular in the city to those who can command a fair amount of leisure. In Bruntsfield, Merchiston and Dalry villas and tenements have also been run up, and in these districts, as in Morningside, the feuing spaces within the municipal boundary are being rapidly overtaken.

As indicated already, there has been plenty of employment in the building trades during the year, and in every branch, with the single exception of the bricklayers, an advance has been conceded and maintained.

PATENTS.

[This List of Patents is compiled specially for this Journal by Mr. G. H. Rayner, of the firm of Rayner & Co., Consulting Patent Agents, 37 Chancery Lane, London, W.C. from whom all particulars and information relating to Patents may be had gratuitously.]

APPLICATIONS FOR PATENTS.

25021. Samuel Naylor, for "Improvements in water-heating and circulating apparatus for domestic fireplaces."
 25065. Carl Wicke, for "Improvements in roofing tiles or slabs."
 25118. Lewis Cass Miller, for "Improvements in sash fasteners."
 25167. Lambert Mulkay and Joseph Mulkay, for "Improvements in and relating to flushing apparatus."
 25253. William Fowler, for "A new sash-cord fastener."
 25269. Otto Ferdinand Jonath, for "Improvements in the construction of ceilings."
 25282. Josiah Weldon, for "Improved device for retaining window-sashes in any position."
 25291. Hugo John, for "Improvements in and connected with chimney-cowls."
 25229. Thomas Sumner, for "Improvements in window-blind fittings."
 25364. Edwin Oliver Read, for "Improvements in window-catches."

ART PLATES FROM "THE ARCHITECT."

Awarded Gold Medals, International Health Exhibition and Architectural and Building Trades Exhibition (1889).

PROOFS on PLATE PAPER of the following Illustrations which have appeared in "THE ARCHITECT" can now be obtained in a separate form suitable for Framing.

THE MARTYRDOM OF ST. STEPHEN. By E. J. POYNTER, R.A. Size, Forty Inches by Fifteen Inches. Price One Shilling. Free by post, carefully packed inside patent roller, One Shilling and Three Pence.

"AND THE SEA GAVE UP THE DEAD." By Sir FREDERIC LEIGHTON, President of the Royal Academy. A few Proofs of this Fine Art Plate can be obtained (if ordered at once), price Two Shillings each. Free by post, carefully packed inside patent roller, Two Shillings and Two Pence.

THE BANQUET. The well-known and beautiful Chromo-Lithograph by H. STACY MARKS, R.A. Size, Thirty-nine Inches by Fifteen Inches. Price One Shilling. Free by post, carefully packed inside patent roller, One Shilling and Three Pence.

1. AN OFFERING TO CERES. 2. THE EDUCATION OF BACCHUS. 3. MINERVA VISITING THE MUSES. 4. JUDGMENT OF MIDAS. By W. HAMILTON. Size of each plate, Forty Inches by Fifteen Inches. The whole forming a very beautiful Frieze in Bartolozzi Mezzotint. Price per set, Six Shillings on Proof Plate. Free by post, carefully packed inside patent roller, Six Shillings and Six Pence.

THE HISTORY OF JOAN OF ARC. By M. JULES EUGENE LENEVEU. From the Wall Painting in the Panthéon, Paris. Four Pictures on one Plate. 1. Domremi: Inspiration. 2. Orleans: Struggle. 3. Reims: Triumph. 4. Rouen: Martyrdom. Size Forty Inches by Fifteen Inches, on Proof Plate. Price, Two Shillings. Free by post, carefully packed inside patent roller, Two Shillings and Six Pence.

THE WATERLOO HEROES. By J. P. KNIGHT, R.A. Dedicated, by Special Permission, to VISCOUNT WOLSELEY, K.P., G.C.B. Proofs, price One Shilling each (thin Plate Paper). Proofs (Special), price Two Shillings and Six Pence each (thick Plate Paper). Size, Twenty Inches by Thirty-six Inches. Framed and Glazed in Oak, Complete, One Inch, Twelve Shillings each. Ditto, One and a Quarter Inch, Fourteen Shillings each. Ditto, One and a Half Inch, Seventeen Shillings each.

THE TOILERS OF THE DEEP. Two Tinted Ink Photographs. Size, Eighteen and a Half Inches by Thirteen and a Half Inches. Price Two Shillings. Free by post, carefully packed inside patent roller, Two Shillings and Three Pence.

JOHN SELL COTMAN'S PICTURES, lately on Exhibition at the Burlington Fine Arts Club. The Plates are uniform in size, Twenty-one Inches by Fifteen Inches. The Titles are as follows:—1. Rouen from Mount St. Catherine. 2. Breaking the Clod. 3. View in North Wales. 4. Norman Arches. 5. Byland Abbey. 6. Norwich, from the Cromer Road. 7. Dewy Eve. 8. Mousehold Heath. 9. Cader Idris. 10. Castle Eden Dean, Durham. 11. Bamborough Castle. 12. The Interior of Norwich Cathedral. 13. Mountain Pass in the Tyrol. 14. Postwick Grove.

The price of the Set is Twelve Shillings and Six Pence; by post, carefully packed in patent roller, Thirteen Shillings. Kindly order early, as only a limited number of proof copies can be obtained.

May be obtained from all Newsagents, Booksellers, Messrs. W. H. SMITH & SON'S Bookstalls, or from the Publisher, P. A. GILBERT WOOD, 175 Strand, London, W.C.

THE
Architect and Contract Reporter.

NEW READING CASE.

To Librarians of the Public Libraries and Reading-rooms.—A new handsome Reading Case can be supplied at a nominal charge of 2s., by post 2s. 6d., on early application to the Publisher, 175 Strand, W.C.

SPECIAL NOTICE TO THE TRADE AND OTHERS.

[Extract from a lecture on Architects' Libraries by Professor T. Roger Smith, F.R.I.B.A., at University College, October 10, 1893.]

"Lastly, let me recommend the back volumes of the professional journals. In the course of years all sorts of architectural topics come up in the public press and before the professional societies, and if you hunt through the indexes of these publications when you are seeking for information which eludes you in books, you will often be rewarded."

There has been a considerable demand for the back numbers of *The Architect* during the last three or four months, which we have no doubt has arisen from the remarks made by Professor Roger Smith, as contained in the above quotation; but the consequence has been that our stock of back numbers is getting very low, and consequently, in future, the charge for back numbers of previous date to January 12, 1894, will be 6d. each.

A few of the back volumes may still be had, price 12s. each.

EDITORIAL NOTICES.

The authors of signed articles and papers read in public must necessarily be held responsible for their contents.

No communication can be inserted unless authenticated by the name and address of the writer—not in every case for publication, but as a guarantee of good faith.

Correspondents are requested as much as possible to make their communications brief. The space we can devote to Correspondence will not usually permit our inserting lengthy communications.

TENDERS, ETC.

As great disappointment is frequently expressed at the non-appearance of Contracts Open, Tenders, &c., it is particularly requested that information of this description be forwarded to the office, 175 Strand, London, W.C., not later than 5 P.M. on Thursdays.

SLADE, TEMPLETON & CO., 15 NEW BROAD STREET, E.C.

ART PLATES FROM "THE ARCHITECT."

Awarded Gold Medals, International Health Exhibition and Architectural and Building Trades Exhibition (1889).

PROOFS on PLATE PAPER of the following Illustrations which have appeared in "THE ARCHITECT" can now be obtained in a separate form suitable for Framing.

THE MARTYRDOM OF ST. STEPHEN. By E. J. POYNTER, R.A. Size, Forty Inches by Fifteen Inches. Price One Shilling. Free by post, carefully packed inside patent roller, One Shilling and Three Pence.

"AND THE SEA GAVE UP THE DEAD." By Sir FREDERIC LEIGHTON, President of the Royal Academy. A few Proofs of this Fine Art Plate can be obtained (if ordered at once), price Two Shillings each. Free by post, carefully packed inside patent roller, Two Shillings and Two Pence.

THE BANQUET. The well-known and beautiful Chromo-Lithograph by H. STACY MARKS, R.A. Size, Thirty-nine Inches by Fifteen Inches. Price One Shilling. Free by post, carefully packed inside patent roller, One Shilling and Three Pence.

1. AN OFFERING TO CERES. 2. THE EDUCATION OF BACCHUS. 3. MINERVA VISITING THE MUSES. 4. JUDGMENT OF MIDAS. By W. HAMILTON. Size of each plate, Forty Inches by Fifteen Inches. The whole forming a very beautiful Frieze in Bartolozzi Mezzotint. Price per set, Six Shillings on Proof Plate. Free by post, carefully packed inside patent roller, Six Shillings and Six Pence.

THE HISTORY OF JOAN OF ARC. By M. JULES EUGENE LENEPVEU. From the Wall Painting in the Panthéon, Paris. Four Pictures on one Plate. 1. Domremi: Inspiration. 2. Orleans: Struggle. 3. Reims: Triumph. 4. Rouen: Martyrdom. Size, Forty Inches by Fifteen Inches, on Proof Plate. Price, Two Shillings. Free by post, carefully packed inside patent roller, Two Shillings and Six Pence.

May be obtained from all Newsagents, Booksellers, Messrs. W. H. SMITH & SON'S Bookstalls, or from the

AMERICAN NOTES.

THE *Southern Lumberman* gives the following solution of fire from steam pipes:—Neither ordinary live steam nor "superheated" steam will heat a pipe thick and strong enough to convey it to a degree sufficient to produce a fire on wood, however dry. It will not even set charcoal aglow or in a blaze. But dry charcoal, when the heat is removed from it, being nearly pure carbon, will absorb oxygen from the air under favourable conditions so rapidly as to produce active combustion, that is, a glow or a blaze. The process of the origin of a fire from a steam pipe is:—The heat from a steam pipe will in the course of time char or, as the chemists say, carbonise wood in contact or close to it. When this charring process extends to any depth in the wood it presents a surface full of fissures and cracks, thus exposing a large section to the action of the air. This process of charring drives the oxygen out of the charred portion and keeps it out while the heat is kept up. When the heat is removed the charcoal reabsorbs oxygen from the air, and if this action is rapid enough in a dry atmosphere combustion is the result. This explains why fires in steam plants and buildings heated by steam that originate from steam pipes always occur after the pipes have cooled, generally during the night.

A SERIES of tests have, the *Railway World*, Philadelphia, says, been recently made on the Philadelphia, Newtown and New York Railway, a division of the Philadelphia and Reading Railroad, about eight miles of which are equipped with the block system of the Audible Electrical Block Signal Company, of Philadelphia. This system enables the engineer, by the ringing of the bell in the cab of the engine, to know when entering a block that the block is or is not clear of obstruction. The system is arranged by equipping the road in the following manner:—Two plates of iron, about 6 inches wide and 30 feet long, are fastened to the ties between the rails a sufficient distance apart to avoid contact with the water-scoop of the locomotive. In a double-track road there would be four of these plates, two to each track. Two of these plates are placed at the end and two at the beginning of each block, with about 100 yards between the blocks. They are connected with a wire, which is buried about 4 feet below ground to remove it from damage by section bands in placing or tamping ties. This wire reaches to the nearest telegraph pole, and is connected to the line wire by a similar plate at the end of the block, and from that block connects

WINSOR & NEWTON'S

"Waterproof"

INDIAN INK.

This new preparation—made from genuine Indian Ink—has been introduced to meet the requirements of those Artists, Architects and Designers who wish to lay washes of colour over drawings in ink.

Unlike many so-called Indelible Inks, "Waterproof Indian Ink," when dry, will be found absolutely unaffected by subsequent wetting.

 Johannesburg, Bilbao, and Rotterdam.

with the rail of the section ahead, each section being insulated by wooden fishplate and insulation. The engine is equipped, just behind and underneath the cow-catcher, with two copper brushes, so arranged as to come in contact with the plates in passing over them. These brushes are connected by insulated wires to two batteries on each side and underneath the cab, and these batteries are connected to the gong inside of the cab. The battery underneath the engineer's side of the cab is the active battery. The one under the fireman's side of the cab is the reserve battery, used only, in case of neglect, if the active battery should be exhausted. These batteries are the only electric force used in the system, and are in use only when an alarm is given. The engineer, on hearing the signal, knows that the block ahead of him is obstructed, and remains there until the bell ceases ringing, showing that the block is clear, or proceeds with caution, as may be decided by orders given by the superintendent of the road. Any metallic connection between the rails of a block so equipped, such as would be given by the two wheels and axle of a car on the block, a wire stretched across the two rails, or any other metallic connection, in case of emergency, will give a signal of danger to an approaching train by ringing the gong in the cab. Precautions are also taken against the opening of switches or the overhanging of a train in entering or leaving a siding. The system of signalling only becomes dumb by the absolute severance or parting of the line wire between blocks, and this is guarded against by a ground wire, which is placed between the iron plates on leaving and entering a block. The merits of tests of visible and audible danger signals in the block system are receiving a good deal of attention from the operating departments of our railroads, and if an audible signal is a desirable one, the company controlling this system seem to have reached great perfection and simplicity in their method. While visible signals cannot be seen during fog, snowstorms, or other unfavourable weather, the audible signal can be relied on, irrespective of atmospheric conditions. It is well adapted to tunnels, curves and cuts.

A RATHER interesting view on the consumption of timber by railways is that of the *Lumber Trade Journal*, which says:—"To one who is familiar with the tracts of timber tributary to the railroad, it is surprising how fast they are being cut back. Where but a short time since the line of forest closely crowded the iron track, it has now vanished with a celerity that to one not on the ground seems somewhat akin to magic. This is making it necessary to build logging roads farther back into

the country, until, in some instances, these unpretending spurs begin to assume the dignity of railroads, in so far as mileage is concerned, at least. This ceaseless slaughter of timber is not caused by prospective gain or a desire for the accumulation of wealth. In many cases it is the effort of necessity. Those who are inclined to blame millmen—and they are many—for this apparently ruthless slaughter of standing timber are in the wrong. The man who prefers to cut down his trees to going into liquidation and perhaps bankruptcy is not to be blamed."

INSTITUTION OF ELECTRICAL ENGINEERS.

THE ordinary general meeting of this body took place, under the presidency of Mr. Alex. Siemens, at the Institution of Civil Engineers, Great George Street, Westminster. Following the presentation of awards to Mr. Wilkinson for his paper on "Electric Tramways in the United States and Canada," to Mr. Allingham (student) for a paper on "Electric Batteries," Mr. Hoadley obtaining the Salomans scholarship, a vote of thanks to Mr. Siemens, the retiring president, was accorded on the motion of Professor Ayrton, seconded by Sir David Salomans. Mr. R. E. Compton, the newly elected president, then took the chair, and delivered an inaugural address, speaking mainly from a mechanical engineering point of view. He expressed his belief that the great development of modern electrical engineering dated from the time when the mechanical engineer first took in hand the design and construction of dynamo-electric machinery. Still, much was due to the impulse given to the progress of electrical engineering by the invention of the incandescent lamp by Swan, Stern and others. In the course of his address the president said that quite recently the attention, not only of electrical engineers, but also of the general public, had been directed by several accidents to the dangers attached to electrical conductors laid in the streets. In many cases these dangers were not properly attributed to the electric conductors themselves, but to the presence of gas in the soil through which those conductors passed. Wherever any space existed into which this gas could infiltrate; an explosive mixture might be formed which might be fired either by an electric spark from the conductors themselves, or by contact with a match dropped by a smoker. He, however, did not think that there was any reason for the public to unnecessarily alarm itself. In the vast majority of cases, where the system of conductors was continuously inspected for traces of gas, no accidents of any kind had occurred.

VARIETIES.

At the meeting of the Glasgow Philosophical Society Professor A. H. Sexton, Glasgow and West of Scotland Technical College, read a paper on "Aluminium." Aluminium, he said, might be regarded as a very valuable addition to our meagre list of useful metals, and one of which increasing use would be made as time goes on; aluminium would certainly not supersede iron and steel for constructive purposes on a large scale. It would, however, be largely used for lighter articles where strength was not so important, and where lightness or resistance to corrosion would be valuable. It was likely to be very largely used for domestic purposes. It was enormously cheaper than silver, little, if any, dearer than nickel or German silver, and therefore it was likely to be much used for ornamental purposes. There was no doubt that the use of the metal had a very promising future.

The Dumfries Council has decided to consult an engineer to be named by Sir William Arrol regarding the condition of the Suspension Bridge, which was severely shaken by the recent storm.

At Macclesfield a Local Government Board inquiry has been held regarding the proposal of the Macclesfield Corporation to borrow 60,000*l.* for the purpose of a main drainage scheme.

The death has taken place of Mr. William Vawdrey, C.E., engineer to the South Staffordshire Waterworks Company, at his residence, 18 Chad Road, Edgbaston. The deceased was the second son of the late Rev. A. A. Vawdrey, many years vicar of St. Agnes, Cornwall, and he served his apprenticeship in practical engineering with the firm of Harvey & Co., of Hayle, Cornwall. After leaving Hayle Mr. Vawdrey was for two years in the Royal Navy, which he quitted on obtaining the appointment of engineer to the South Staffordshire Waterworks Company, a post which he held up to the time of his decease, a period of thirty years.

The *Manchester Guardian* says a piece of a section of one of the giant trees of the mountains of Fresno County, California, has lately been sent to the Museum of Owens College by the South Kensington authorities. At the distance of 8 feet from the ground the trunk measured 62 feet in circumference, and at the ground the tape line showed 90 feet girth. The height was close to 300 feet, the branches commencing more than 200 feet from the earth. It was estimated that the trunk would yield 400,000 feet of lumber. The group of

sequoias from which the tree was cut, situated in the locality known as the Converse Basin, contains, it is calculated, sufficient timber to keep the local saw-mills running for fifty years at a daily output of 130,000 feet during the summer months. A section of the same tree, which was shown at the Chicago Exhibition, and has lately been removed to the New York Museum of Natural History, weighs over 30 tons. It is 4½ feet in thickness.

At the meeting of the Manchester Association of Students of the Institution of Civil Engineers, Mr. A. Ross, C.E., in the chair, Mr. R. H. Clayton read a paper on "Mortars and Cements as applied to Structures." It was a matter of regret, the author said, that no concise and thorough information existed as to the classification and locality of good limestones in this country. Methods of distinguishing the nature of limes by their behaviour under certain tests were described, and instances cited where mortar composed of unslacked lime had seriously injured works by forcing masses of masonry entirely off their beds. Specifications of limes, cements and aggregates for mortars were given, with the results of various tests referring to the same. The qualities of Portland cement were briefly discussed, and the paper concluded with some remarks on the danger arising from the presence of "free lime" in Portland cements.

The course of lectures at the Royal Botanic Gardens, Edinburgh, organised by Professor Bayley Balfour, Regius Professor of Botany, for young practical foresters and gardeners, have proved, according to the *Scotsman*, of a very successful character. They are now in their third session. The first of a series of lectures on the valuation of woodlands and the disposal of their produce, with its transport, conversion, qualities, and uses, has been given by Mr. Andrew Slater, Haystoun, Peebles, a well-known authority on the subject, and among other lectures arranged for this session are short courses on draining and fencing, on landscape gardening and on decorative gardening. The branch of the subject dealt with by Mr. Slater was the measurement of rough timber, the valuation of growing woods at different stages of their existence, and the disposal of wind-blown timber.

SERIOUS damage has been done at Lossiemouth. Through the force of the tide two breaches, from 30 to 40 yards wide, were made in the sea-wall lately built by the Great North Company, as also a smaller one. The south pier of the harbour has also been considerably damaged. The damage to the sea-wall, the harbour and the boats is estimated at 3,000*l.*

ALBERT WORKS, ALBERT EMBANKMENT, LONDON, S.E.

THE Local Government Board have granted permission to the Ipswich Town Council to borrow 18,500*l.* for the purchase and laying out of Christchurch Park, which is beautifully situated in the heart of the town, as a public recreation ground.

At the meeting of the Port Glasgow Town Council a letter was submitted from Mr. Joseph Russell, shipbuilder, accompanied by a cheque for 600*l.* to put the baths and wash-houses in good working order. Mr. Russell originally gave 5,000*l.* to the Town Council for the purpose of erecting the public baths and wash-houses, but the total cost of erection and equipment has turned out to be 5,485*l.*

A CORRESPONDENT of the *Parish, District, and Town Councils Gazette* (which promises to be a useful addition to the municipal journals) points out that the object of section 46 of the Parish Councils Act "is to prevent a parish councillor from obtaining any personal pecuniary advantage by holding office, and as in certain cases, at any rate, that object might be defeated if councillors supplied goods to trustees appointed by the Council, tradesmen would be well advised if they either resigned their seats or declined the orders. A parish councillor should be above suspicion."

MR. HALDANE puts the prairie value of London at 16,000*l.* a year. The actual rent paid for the bare soil of London is, however, almost exactly 16,000,000*l.*—or a thousand times as much.

It is stated that Sir Algernon West has intimated to his neighbours at Wanborough, Guildford, that he intends to erect a Working Men's Institute in the village as a memorial to the late Lady West.

At Middlesbrough fifty-five applications have been received for the post of borough surveyor. The following six names have been selected for consideration:—Mr. T. D. Cooper, assistant borough surveyor, Middlesbrough; Mr. T. W. Stainthorpe, surveyor to the Eston Urban Council; Mr. Frank Baker, city surveyor, Canterbury; Mr. S. E. Burgess, borough surveyor, Stoke Newington; Mr. M. Scott, borough engineer, Thornaby; and Mr. J. E. Stafford, Blackburn.

At the conversazione of the Midland Institute, Birmingham, just held, among other exhibits was a portion of the collection drawings and plans of ancient British and Roman camps

recently presented to the Archæological Section by Miss Lines, of Worcester, in memory of her father, the late Mr. H. H. Lines, by whom the drawings were made. These drawings are of extreme antiquarian interest, and it is believed that there is no similar collection in existence.

At the meeting of the Glasgow University Court, Lord Provost Bell moved—"That in view of the erection of art gallery and museum buildings by the Association for the Promotion of Art and Music in the City of Glasgow, it be remitted to the museums committee to consider if it is advisable to arrange therein for accommodation of the Hunterian Museum or any portion of it." The motion was adopted.

At the meeting of the Coventry City Council, on the recommendation of the electric-light committee, it was decided to accept the tender of Messrs. Chamberlain & Hookham, Birmingham, for the supply of meters, each meter to be certified as efficient by the Electrical Standardising and Testing Institution, the specification for the meters having been prepared by Mr. R. Hammond, the consulting electrical engineer to the Corporation.

GREAT inconvenience has been caused to vehicular traffic in the neighbourhood of Preston by the partial collapse of both sides of one end of the bridge over the Ribble at Walton-le-Dale. In connection with some extensive sewerage works for that village, tunnelling has been carried on under the bridge. The recent frost and subsequent rapid thaw caused the bridge to subside, leaving only just room for a horse and trap or other light carriage to pass over in the middle of the roadway. Even that is in such a dangerous state that heavy traffic is prohibited. The bridge was built in 1779-81, and cost 4,000*l.*

At the meeting of the Paisley Police Commissioners, Provost Mackenzie stated that the arrangements in connection with the formal handing over of the baths in Storie Street as a gift to the community had now been completed, and he moved that they forward to Mr. Dunn, writer, agent for the donors, a vote of thanks recognising their kindness. In addition to the baths, Mr. James Coats and those associated with him, he might add, had also handed over a sum of 850*l.* Ex-Bailie Smith seconded the motion, which was supported by ex-Provost Clark, and unanimously adopted.

TRADE NOTES.

THE patent folding partitions, of which Messrs. Peace & Norquoy are the sole makers, have been adopted by the Rochdale School Board in the new Spotland Schools, under the superintendence of Mr. T. Townsend, architect, Rochdale.

THE city authorities of Carlisle have placed a new illuminated turret clock, showing the time upon four external dials 5 feet 4 inches each in diameter, in the tower of the "Tullie House" Fine Art Gallery. The clock is made from the designs and plans of Lord Grimthorpe and has all the latest improvements inserted by Messrs. W. Potts & Sons, clock manufacturers, of 13 Guildford Street, Leeds, and 22 Collingwood Street, Newcastle-on-Tyne—makers of the Corporation Markets and North-Eastern Railway Company's illuminated clocks, Carlisle—from instructions received by them from the city surveyor, Mr. W. Howard-Smith, C.E.

THE Tilehurst Board Schools, Reading, are being warmed and ventilated by means of Shorland's patent Manchester grates and patent Manchester stoves, the same being supplied by Messrs. E. H. Shorland & Brother, of Manchester.

WE are informed that Mr. Swaine Bourne, of Birmingham and London, artist in stained glass, has taken into partnership his son, Mr. Kendrick Swaine Bourne, and the firm will be known as Swaine, Bourne & Son, henceforth. Mr. Kendrick Swaine Bourne is already known for his artistic abilities, and that is a guarantee for the continued success of the firm in producing art works of the highest excellence.

THE business and undertaking, including stock and plant, of Elliot's Patent Stove Company, Limited, were sold by auction at the company's premises, Rye Harbour, Sussex, as a going concern, for 4,000*l.*, by Mr. Wm. Thos. Smith, auctioneer and surveyor, Rye and Tenterden, on Tuesday, the 15th inst.

IN consequence of Messrs. J. & P. Coats, thread manufacturers, Paisley, having conveyed to the trustees of the Peter Brough Bequest Fund the site and buildings in George Street formerly occupied by them as dyeworks, together with the sum of 3,000*l.*, for the purposes of a technical school, it has been decided to hand over the whole property, funds and effects of the Paisley Government School of Art to the governing body of the Technical School.

THE Paisley Police Commissioners have resolved to proceed with the extension of the public baths. The estimated cost of the extension, according to the plans, is 4,500*l.*

WE find that Mr. W. C. Bryant, of Main Street, Birmingham, is exhibiting some splendid marble chimneypieces at the Yorkshire Trades Exhibition at Sheffield suitable for drawing-rooms, in statuary Pavenazzo and Languedoc, Rose Castille and Rose Vif; and dining-room chimneypieces in Griotte St. Remy, Rouge Royal, St. Annes, and Irish green. Mr. Bryant holds the largest stock of marble chimneypieces in the United Kingdom, and is the representative of the well-known firm of Devillers & Co., of Belgium, France and Italy, whose finish and quality of marble are superior to any other marble house in the world. Mr. Bryant gives special attention to architects' designs, and does a large business in marble work for public buildings, &c.; also in enamelled slatework of every description. We lately had the opportunity of seeing some of the chimneypieces in Birmingham.

TECHNICAL TRAINING.

THE annual meeting and distribution of prizes in connection with the Manchester Municipal Technical and Art Schools was held on Tuesday evening in the Town Hall, under the presidency of Mr. Alderman Hoy (chairman of the technical instruction committee of the City Council). The principal prizes awarded to students as the result of recent examinations were distributed by the Bishop of Manchester. Sir Henry Roscoe, M.P., in a letter excusing his attendance, stated:—"All friends of technical education must be gratified by the progress which has been made throughout the country, and we in Manchester may well be proud of the position which our school has won for itself—a position which I do not hesitate to say is a unique one in the country." Letters regretting inability to be present had also been received from Mr. R. D.

Darbishire, Principal Ward, Mr. A. J. Balfour, M.P., Mr. W. H. Holland, M.P., and others.

The report, which was read by Mr. Reynolds, secretary, stated that the results of the examinations for the session 1893-4 compared, on the whole, favourably with those of the previous session. In May 1893, 717 individual students were examined in science, and 743 certificates were gained; in 1894, 693 students examined gained 780 certificates; in 1893, six first-class honours, thirteen second-class honours, eighty-seven first-class advanced, 279 second-class advanced, 322 elementary pass, as compared with nine first-class honours, ten second-class honours, eighty-eight first-class advanced, 225 second-class advanced, and 402 elementary pass, showing an increase of three first-class honours, one first-class advanced, and eighty pass for first-class elementary, with a decrease of three second-class honours, fifty-four second-class advanced. Two Queen's medals in the honours stage had been awarded, being the same as in 1893, and one Queen's Prize, against two in 1893. One Royal Exhibition of 50*l.* per annum for three years had been awarded, against two in the previous year. The results of the examinations conducted under the auspices of the City and Guilds of London Institute had again proved highly satisfactory, the school retaining the position it has held for so many years—in fact, since the establishment of these examinations—as the first in the kingdom alike in respect of the number enrolled in the technological classes, the number of subjects taught, the number of students examined and successful, and in the number of medals awarded. In 1894, five silver and thirteen bronze medals were obtained and 23*l.* in prizes; in 1893, ten silver and seven bronze medals, with 27*l.* 10*s.* in prizes. The following were the successful medallists:—F. W. Acheson, cotton weaving; S. B. Bennett, plumbers' work; S. E. Burrows, dressmaking; W. H. Cockcroft, carpentry and joinery; E. A. Coups, lithography; A. Crabtree, cotton spinning; A. E. Follows, cotton dyeing; W. H. Hopwood, coal-tar products; J. Mottram, carpentry and joinery; A. Ramsden, cotton dyeing; F. Riley, calico and linen printing; H. F. Robinson, coal-tar products; E. F. Roby, coal-tar products; H. Stoddard, cotton weaving. At the commercial examinations of the Society of Arts held in March, 1894, ninety-four students were examined, of whom eighty-six received certificates. The number of students examined by the Union of Lancashire and Cheshire Institutes in 1894 was 361, who were awarded 343 certificates. J. H. Harrison, a day student, gained a Lancashire County Council

scholarship, value 60*l.* per annum for three years, tenable at the Owens College, and H. Ingram, W. J. Mitchell, and T. C. Elliott gained Lancashire County Council evening exhibitions of 10*l.* for one year. The following students of the school gained Manchester County Council scholarships, value 30*l.* per annum for three years, tenable at the Municipal Technical School:—J. L. Bowers, E. Crompton, A. Goodbehere, F. Nasmith, W. H. Omblor, N. Roberts, J. Rundbaken, and J. D'Ewart, T. C. Elliott, W. B. Green, evening exhibitions, value 10*l.* per annum for two years. W. Spensley gained a Manchester County Council evening exhibition, value 10*l.* per annum for two years, tenable at the Owens College. The local prizes were awarded as follows:—Mechanical engineering department: First year's course, 1, J. C. Wilson; 2, H. Pier-son; 3, A. Holden. Electrical engineering department: Second year's course, F. O. L. Chorlton; third year's course, J. Landstein. Chemical department: First year's course, 1, R. E. Grayson; 2, Margaret A. Pepper; second year's course, 1, A. Ramsden; 2, L. Anderson; 3, J. E. Doodson. Spinning and weaving department: First year's course, 1, A. Crabtree; 2, G. W. Phillips; 3, W. Slater; second year's course, 1, F. Collier; 2, W. G. Warburton. Home work prizes were also awarded to A. Crabtree and W. G. Warburton. The free scholarship, value 6*l.* for one year, in the Manual and Commercial School was awarded to C. H. Sankey, and prizes for efficiency were granted to R. Lord, W. Warmisham, H. Rowland, T. Weir, A. C. Brock, P. E. Omblor, A. K. Swain, C. W. Moore, and J. J. Edmondson. Forty-four students had gained forty-nine prizes in the advanced and honours stages, and 164 students 188 prizes in the elementary and ordinary stages of science and technology, having obtained first-class certificates and made twenty-five attendances during the session ending May, 1894. The Heywood local exhibition of 50*l.* for one year (due to the generosity of Mr Charles J. Heywood) had been gained by W. C. Laidler, who elected to hold it at the Owens College. J. H. Hardy, who gained the exhibition in 1893, had succeeded in gaining a Royal exhibition value 50*l.* for two years, tenable at the Royal College of Science, Dublin; he had also gained the second prize in theoretical and practical physics at that college.

The Chairman said they were privileged to have the Bishop of Manchester to distribute the prizes.

The Bishop, before distributing the prizes, delivered a short address. We all knew, he said, that technical instruction was a commercial necessity of our position. England could not

feed herself unless she maintained her present commercial and industrial supremacy, and she could not maintain that supremacy unless she was able to compete with the well-instructed inhabitants of Continental states, and she would never be able to do that unless our young men possessed a large store of technical knowledge and skill. But technical instruction was not only necessary to our commercial position: it was also of the highest advantage to the individual students. There was nothing more dreary and uninteresting than the mechanical repetition of processes which we did not understand. As he made an inspection of the various Church schools of the Manchester diocese he found that the only children who gave him bright answers in vulgar fractions were those to whom their masters had explained the reasons for the rules which they applied. Now he was told that it was the main aim of these technical schools to teach people the scientific principles which regulated all the processes of their industry. When the students understood those principles, they would be interested in their work; they would have an added dignity in their work, and by the suggestion of improvements in their processes they would become a distinct advantage both to the students and to the community which was happy enough to possess them. Just think of the number of hours all of them had to spend in their daily work. They could easily see what an enormous advantage it was, how valuable, almost beyond computation, was the power in the hands of our young people of making that daily work an improvement and a delight. Then not only would a man make better work, but, what was of far more importance, the work would educate and delight the man. Then he dared say there were certain indirect advantages of technical instruction which might not have suggested themselves to many of his hearers. They knew that one of the most important and interesting of the movements of modern times was the attempt to increase the wages of manual labourers. He believed that many of the movements which were now popular would not tend to attain that end, but he had no doubt at all that the increase of technical instruction would promote it greatly. In the first place, it would tend to make labour more efficient by the improvement of the labourer, and by the improvement of the processes of work, so that we should be able to compete on easier terms with those less instructed races who were satisfied with lower wages and longer hours of work. Then, in the next place, we should be able by increased technical instruction to cheapen the cost of managing our great industrial concerns. How did they think, the standard of industrial proficiency being the same,

they could cheapen anything? By simply increasing its quantity. Why was it that during the last thirty or forty years the price we paid for the use of money had been declining? Why was it, for instance, that the interest upon municipal bonds had diminished from 5 per cent. to 3 per cent.? How was it that Government, which used to be obliged to pay $3\frac{1}{2}$ per cent. for Consols, was now enabled to borrow money at $2\frac{1}{4}$ per cent., speedily to be reduced to $2\frac{1}{2}$ per cent.? It was owing to the amount of capital competing for investment. So they saw just in proportion to the increase of thrift was the diminution of the price people paid for money, and therefore when capital was cheap and men paid less for its use there was a certain margin of profit which might be added to the wages of the labourer. Well, it was just the same with industrial instruction. A little time ago he was speaking to a large body of people who had confederated themselves together for the promotion of co-operative production, and he had to say to them: "Gentlemen, you have constantly failed in your attempts to make this a means of improving the position of the working-class, and I believe one of the main reasons why you fail is that you have not got sufficiently skilled management, and the reason that you have not got it is that you won't pay the market price for it." Now, the market price at present happened to be rather high, because there were but few skilled managers of large concerns. Now if by technical instruction they enabled young men to apply their natural ability to the management of great concerns, there would be more skilled managers in the market competing for employment, and their price would go down, the cost of management would be less, and if that was less it might be possible to add what was saved to the wages of the labourer. So if one class lost something, the class to which many of his hearers belonged gained a great deal. Probably some of those who intended to be managers did not like the prospect of a reduction of the price. To them he had one or two things to say. First of all, it was far more important to have a large number of persons moderately well paid than a small number of persons extravagantly paid. No doubt there would be fewer prizes for persons who were blessed with splendid genius, but then we were not all of us possessed of splendid genius. The majority of us were persons of very moderate talent, who were doing the best we could to improve our talent. Well, if by the cheapening of the cost of management a larger number of co-operative productive societies could be made successful, there would be many more managers wanted, and therefore a con-

siderable number of the students might look forward in the future to positions of great honour which would be fairly remunerative. Another thing he had to say was this. He trusted that our education was not only intellectual, but even more—that it was ethical. Now, if it be so, they would know that the noblest man was not the man who earned the greatest sum of money, but the man who blesses the largest number of his fellow-creatures. If they wanted to have their lives great lives, if they wanted to do as much good to others as possible and to gain as high an amount of happiness for themselves as possible, if they wanted to make this poor world better for the work they had done in it, then they would adopt as the principle of their lives this great principle—that the highest reward of a man's life is the reward of doing good to the greatest number of his fellow-creatures. Now it was because he believed that technical instruction would put into their hands the means of doing this, far more than for any other reason, that he heartily wished success to these most promising institutions. The prizes were then distributed.

ACQUIRING LAND FOR PUBLIC PURPOSES IN NEW SOUTH WALES.

THE following case, which has been tried in the Supreme Court of New South Wales, indicates that the Corporation of Manchester is not the only public body that is expected to pay an extravagant price for land. The action in question was brought by Mr. Alexander Amos, railway contractor, against the railway commissioners of New South Wales, to recover the sum of 209,800*l.* for the resumption of a little over twelve acres of land in the district of Bowral. The land in question, which was resumed by the Government for the purpose of quarrying stone and ballast for railway construction, was situated at a place called The Gib, between Mittagong and Bowral, and not far from the railway line. The plaintiff claimed that this land or quarry contained some of the best building stone in the colony, and that there were 15,000,000 tons of more or less valuable stone down to the railway line. The land included a hill which rose to a height of 200 feet. For the first part it had a gentle incline, then there was an abrupt ascent for a distance of 50 feet, then another gradual ascent, terminating with another precipitous face. This hill contained some of the best building stone known, and which was rapidly supplanting Victorian bluestone, owing to its superior strength and

durability. It was also capable of receiving a high polish, and its contiguity to the railway line made the property still more valuable, as a tramway could easily be constructed to it for the purpose of removing the stone. The plaintiff's estimate of the value of the property to him was arrived at by taking a datum point level with the railway line and making a valuation of the first-class stone available above that point. One engineer had computed the quantity of this stone in the hill at 2,921,000 cubic yards, and another at 3,875,000 cubic yards, and as 2½ cubic yards of this stone went to the ton, that would give between 8,000 and 9,000 tons of stone above the datum point, without estimating the stone below. The defendants pleaded that they had valued the property at 1,500*l.*, which had been tendered to plaintiff and refused.

Mr. G. Allen Mansfield, architect, stated that he knew The Gib, where a quantity of trachyte stone existed, and he had used that stone since 1888. It was used in the Australia Hotel, principally in the foundations for the columns. Trachyte was very much harder than Pymont sandstone, and even than granite, and it took a high polish. If a person desired to erect a building of Pymont sandstone at a cost of 20,000*l.*, and he afterwards determined to use trachyte instead, it would cost about 45,000*l.* George M'Crae, city architect, said that trachyte was used to the extent of 4,000 cubic feet in the bases of the Belmore market. It was also used for the portico of the new portion of the town hall and the new markets in George Street, from the ground to the shop floors. He believed it was also extensively used by the Municipal Council for kerbing and guttering. Although expensive to work, trachyte being very durable, was largely used for base-courses and rough work. It was harder and more durable than sandstone or Melbourne bluestone. The first cost of trachyte was greater, but it was cheaper in the end, as it was comparatively indestructible. A building of trachyte would cost about double one of sandstone, but it would last very much longer. In the Centennial Hall, which was finished nine or ten years ago, the sandstone cornices were fretting away, whereas trachyte would not exhibit that defect perhaps for hundreds of years.

William Henry Warren, Challis Professor of Engineering in the Sydney University, said he had tested a block of trachyte, and found it much more durable than sandstone or bluestone. It appeared to be impervious to water, and was not liable to wear away rapidly by friction. For that reason it was the best stone that could be used for ballast purposes on the railways.

157 STRAND, W.C. (Four Doors from Somerset House), LONDON.

The City Surveyor stated that since 1889 trachyte had superseded bluestone for kerbing and guttering and paving for municipal purposes. In 1889 5,991 lineal feet were used, at a cost of 860*l.* 7*s.* 1*d.*; 1890, 4,721 lineal feet, at a cost of 690*l.* 12*s.*; 1891, 13,401 lineal feet, at a cost of 1,943*l.* 2*s.* 7*d.*; 1892, 15,388 lineal feet, 2,626*l.* 11*s.* 2*d.*; 1893, 27,469 lineal feet of kerbing and guttering, 4,367*l.* 11*s.* 10*d.*; and up to September 1894, 7,700 square yards of paving, at 5,186*l.* 10*s.* 8*d.* Evidence was also given of the rent paid to owners of quarries in the same locality as "The Gib," and the value of the stone per cubic yard delivered in Sydney. One witness stated that there was sufficient trachyte in the Bowral district to last for hundreds of years; in fact, it was practically inexhaustible, as it extended over about two miles of country.

John Young said that 150,000 tons per year was a proper output for the plaintiff's property, which should return a royalty of about 16,000*l.* per annum, calculated on the following basis:—6*s.* per ton for first-class stone, 1*s.* 6*d.* per ton for second-class stone, and 6*d.* per ton for spalls or metal, which would give 12,000*l.* for first-class stone, 3,000*l.* for second-class stone, and 1,000*l.* for spalls.

Plaintiff was also examined, and said that he obtained the quarry in 1881, and he knew of the value of the stone when he bought the property. Mr. Richard Teece, manager and actuary of the Australian Mutual Provident Society, was called, and asked to capitalise the present value of a property which would yield 16,000*l.* per annum for fifty years; but the question was objected to, and at four o'clock further argument was adjourned till the following day.

On the second day the question of the advisability of actuarial evidence tendered on the previous day to prove the capitalised value of the property on an estimated income of 16,000*l.* per annum for fifty years was concluded, and the evidence was rejected. Plaintiff's case then closed.

His Honour Justice Innes suggested that the property be given back to the plaintiff and an account taken of the value of the stone removed by the defendants. Payment of the amount could then be made to the plaintiff. On the other hand, if plaintiff upon resuming possession of the land derived any benefit from the tram-line and other works constructed by the defendants, he should allow them compensation for that benefit; if he derived no benefit, plaintiff need allow nothing for it. The adoption of this suggestion would save enormous expense in protracted and most costly litigation—no less than seven

counsel of eminence being in it—and would really be a very fair test of the bona-fides of both parties. Here was a case where a plaintiff was claiming 209,800*l.* for a property which the Government said was not worth 1,500*l.* On the one hand, the Government had no right to take away an inch of the plaintiff's land or an ounce of the stone upon it without making him full compensation for the property of which he was deprived. On the other hand, the public—the taxpayers—might be called upon to pay a sum altogether extravagant and out of all proportion to the value of the property resumed. Now, if this property really was so valuable as the plaintiff alleged, he should either have it back or be compensated for it. It could not be essential to the Government to retain it. It was not like the case of land resumed for some special public purpose, as, for instance, the contemplated enlargement of an already existing public building, where the Government must have the particular piece of land in question for the purpose; and full justice might be done by adopting the suggestion he threw out. The public might then derive some benefit from it eventually by Mr. Amos paying an income tax on 16,000*l.* per annum, or a property tax upon the capital value of property worth, as he alleged, over 200,000*l.* His Honour added that he had often thought that there should be a right, if the Government considered that an extravagant or dishonest claim had been made, to return the property rather than submit the in many cases undoubtedly difficult question of compensation to a jury. This was somewhat analogous to the right which existed in the Customs officers if an importer, in their opinion, dishonestly valued property imported at very considerably less than its real value, to take the commodity and pay the importer the value so fixed by himself. This would in many cases act as a salutary check on attempted imposition upon the public. He must not be misunderstood as suggesting for one moment that the claim of the plaintiff in this case was either extravagant or dishonest. That was not in any way for him to determine or pronounce upon.

Afterwards the judge held a consultation with counsel, and on returning to Court, informed the jury that he had every reason to hope that the matter was in fair train for settlement upon the basis of the main arrangement suggested by him—namely, the restitution of the land. Of course, this was an important matter, and required to be carefully considered. One matter of detail had already been arranged, and he hoped that another detail would also be arranged satisfactorily, so as

Suitable for wherever a Very Powerful, Well Diffused, Soft, Economical, and Easily Managed Gas Light is desirable. Made in Five Sizes.

HONoured WITH SUNDRY IMITATIONS.

Seven years from Invention up to April 1890 over 11,300 sent out. But
Up to the end of 1893, over 23,000 sent out.

A PERPLEXED GAS INSPECTOR.

"There has been so great a reduction in our consumption of gas at Speke Hall, Battersea, since we had your CLAPTON LIGHTS, that the Gas Company declared our meter must be out of order. They have had it examined, and can find nothing wrong."

R. H., London, September, 1893."

The Gas Light also at this Hall is said to be over twice what it was before.

J. C. HALLIDAY,
INVENTOR AND MANUFACTURER,

12 GRAINGER STREET,
NEWCASTLE-ON-TYNE.

to put an end to the necessity of protracted and costly litigation, or of going to a verdict which possibly might not be satisfactory to one side or the other. He said this without in any way disparaging the jury, because the case was a difficult one to decide. Under all the circumstances of the case, he had no difficulty in acceding to the request of counsel for the plaintiff to adjourn until to-morrow, as the interval might be much more profitably utilised in arranging the necessary details of the settlement than in taking further evidence.

The hearing of the case was resumed on the following day, and after a conference between leading counsel for the parties and a reference to His Honour on some material point at issue, the following agreement was arrived at:—"Plaintiff to take back the resumed land. Dr. Sly to take evidence and determine the amount of stone taken from the twelve acres, and allow for same at a fair royalty in view of the value of the stone taken. Defendants to pay amount of such royalty less value of work done by defendants to the quarry which has had the effect of improving the same for quarrying purposes. Costs of action as between party and party to be paid by defendants, and each party to pay their own costs of further inquiry before Dr. Sly."

His Honour said he thought the jury would agree with him that the arrangement was a fair and equitable one, which saved them a good deal of troublesome discussion. Whatever they might have felt in regard to the case, there was always a possibility of injustice being done if it were fought out, whereas, under the arrangement arrived at, no real injustice could happen either to claimant or to the public, who would have to pay the compensation. He was sure that the settlement was a proper one in the interests of both parties.

The foreman mentioned that the jurors were satisfied with the arrangement arrived at.

A juror was then withdrawn and the case terminated.

THE MANCHESTER SHIP CANAL.

A MEETING of the Manchester Association of Engineers was held on Saturday night, when there was a large attendance of members.

Sir E. Leader Williams, the president, after thanking the members for the honour they had conferred upon him by electing him to the chair for the ensuing year, proceeded to

deliver the annual address. He said it had to some extent been customary on these occasions to review the improvements in engineering science since the last address; but on this occasion he should confine himself to the branch of their profession in which he had been most closely engaged. The early history of canals was a matter of some interest. The advantages of inland navigation were obviously so great that the Royal Canal in China was constructed as early as the year 980. Its length was upwards of 825 miles, and with many branches in addition to the main canal. It occupied 30,000 men forty-three years in construction. The Suez and the Corinth Canals almost traversed the same ground that was occupied by early canals of smaller size. In England the Romans constructed canals, one of which—the Foss Dyke Navigation—still was used. It connected the river Witham at Lincoln with the river Trent at Torksey. The introduction of locks enabled canals to be constructed through a country requiring different levels, thus saving great cost in excavation. There was some doubt as to the date of their introduction. Flushes in rivers were used before locks were invented, which appeared to have been in Italy in the fifteenth century. In the year 1481 two brothers of Viterbo, named Domenico, watchmakers, designed a chamber with a double pair of gates for canals, and it was adopted in the Canal della Martesana. No waterway is more important to commerce than the Suez Canal, which was the complete fulfilment of the early canals made across the same isthmus so far back as the reign of Darius. The Suez Canal was the only ship canal of one uniform level without locks, but the failure of the Panama Canal was largely due to M. de Lesseps' attempt to apply this system where it was not properly applicable. During M. de Lesseps' last visit to Manchester he (Sir E. Leader Williams) had several conversations with him in reference to the Panama Canal. The capital had not then been raised for the works of the Manchester Ship Canal, but they were overlooking the site of the canal and docks at Manchester. Discussing the question of locks in ship canals, M. de Lesseps said his success on the Suez Canal was such as to prove that the Panama Canal could be constructed and worked without locks. He (Sir Leader Williams) replied the two cases were not similar. M. de Lesseps' answer was that the English engineers were wrong as to the Suez Canal, and locks were not necessary at Panama. In 1888, however, the original plans of the Panama Canal had to be altered, and eight locks were designed to reduce the amount of the great Culebra excavation. This alteration was too late to save the canal. M. de Lesseps

J. ATTWOOD.

STOURBRIDGE.

The only Attwood in the Trade

did not dispute the advantage of locks on the Manchester Ship Canal, as the raising of the water to a level which admitted of shipping lying on the canal alongside wharves or works at a suitable height above the canal for loading or discharging was, he considered, a great advantage in a canal which was virtually an elongated dock. Sir Leader Williams went on to deal with the construction of the Manchester Ship Canal. The work, he said, was one with which his name was identified, but he should ever remember that the successful completion of the canal was due to the combined energy of men who had given much time and money to the undertaking, and also to the way in which the staff of the company had worked together from first to last. In the course of his description of the canal he pointed out that from Latchford to Manchester (a distance of 14½ miles) the canal was filled with the waters of the rivers Mersey, Irwell, Bollin and Glazebrook. The canal being designed to take the place of the rivers Irwell and Mersey from Manchester to Latchford, it thus became a canalised river, continuing to be the main drain for Lancashire and Cheshire, large sluices being provided at each set of locks to deal with land floods and surplus water. Owing to the sewage of Manchester, Salford and all other towns on the rivers Irwell and Mersey and their tributaries being allowed to flow into the rivers without purification, the state of the water had become very bad. Salford had now completed a system of intercepting sewers, and was about to purify the sewage at works constructed at Mode Wheel. Sewage works were now being constructed by Manchester, and as the turning of crude sewage into rivers or streams was contrary to the law as well as injurious to health, the other towns above Manchester must take immediate steps to prevent their sewage polluting the canal. Some of them had now got this necessary work in hand. He reminded the meeting that when he read a paper on the Ship Canal before the Fourth International Congress of Inland Navigation, held at Manchester in 1890, he said steamers would be able to navigate day or night, using the electric light. This had proved to be correct, even where vessels had not on board the electric light, which was provided as fixed light at the docks and locks. He, however, named ten hours as the time steamers would take to traverse the canal; the result was that time was seldom taken, the passage generally occupying seven to eight hours, passenger steamers even taking considerably less time. Messrs. Burns's steamers working between Manchester and Glasgow had averaged, on 236 passages made during the year 1894, only 6 hours 33 minutes; 117 passages were made at night. He

added that he could see no reason why Lancashire, so famed for its machine-shops, its boiler-makers, and its artisans, could not establish on the banks of the Ship Canal works which should be able to compete with other districts for ship-building. Much had been said and written with regard to the estimates of the canal, and as usual in such cases, the strongest statements had been made by those who were least acquainted with the facts. The original capital of the company was 10,000,000*l.* The Parliamentary estimate for works and land was 7,292,972*l.*; to this must be added 1,780,000*l.*, the cost of the Bridgewater Canal and Mersey and Irwell Navigations, including conveyancing and additional works. The balance had to meet the cost of obtaining the Act, which was very heavy after several years' contests, cost of raising the capital, and the payment of interest during portion of the construction. The works were let to responsible contractors well within the Parliamentary estimate of 1885, but, most unfortunately, the plans had to be approved by numerous public bodies and companies who were affected by them. Alterations of the most serious character had to be carried out, involving great additional expense, some of which were entirely unnecessary, as events had since proved. Great improvements were made in enlarging the area of the docks and putting in locks at Mode Wheel, additional Parliamentary powers being obtained in 1888. Large three-storey transit sheds had been constructed at the docks, and many other works had been ordered that were not in the original plans. Large quantities of land had been purchased in excess of the land estimate, which was a valuable asset, if not immediately available. Owing to the unfortunate death of the contractor, Mr. Walker, the company took over the contracts and the plant, involving a sum of 860,000*l.* that had been advanced upon it, and which by the contract would have been deducted from the payments to the contractor if he had completed the work. The contractor had no floods during the period he was working, but the company had to bear the loss of several floods of the most serious character. The cost of repairing damages to works and plant, pumping out water, and heavy delay to the work, was very large. The last step was to re-let the works to other contractors, and it was obvious that to complete a work under such circumstances enhanced prices had to be paid. If the original plans could have been adhered to, as they would have been if outsiders had not had so much control of them and Mr. Walker had had time to complete his contract, the result to the company would have been very different. The delay caused by his death entailed the payment of additional interest to the

debenture-holders. The works in the estuary, and indeed at all points, involved considerable contingencies, and there could be no doubt that the ordinary amount of 10 per cent. which was added to the estimate for contingencies had proved to be too small; but no engineer could have contemplated that his plans would be so altered, or that the contractor, after doing the part of the work that was most easy, would unfortunately pass away, leaving such a legacy of trouble behind him. Still, the canal was completed; the results of the first year had been to prove its efficient working, and he had not lost his faith in its future. Rome was not built in a day, and it could not reasonably be expected that, amid the severe competition that had to be encountered, even the energetic management that was now dealing with traffic matters could all at once force from hostile or lukewarm traders the business which must ultimately come to the canal, because no large waterway leading to a great manufacturing district could fail ultimately to obtain the traffic which was due to the advantages it offered.

Mr. T. Daniels proposed a vote of thanks to the President for his address, and said there could be no doubt that, had the Ship Canal been constructed forty or fifty years ago, the district between Manchester and Warrington would have presented a very different appearance to-day. He had every confidence that although they would now have to wait for a result which might already have been achieved had there been more enterprise in the past, yet that result would ultimately be forthcoming.

Mr. T. Ashbury seconded the resolution, which was adopted unanimously.

MODEL TENDERING.

THERE cannot be too little secrecy in tendering. In the first place, when full information is given it becomes evident whether dishonest or inadequate prices are accepted. It is constantly said that totals are far too low, and there is consequently a common opinion that the mean between the highest and lowest tenders is usually the fairest, and has the best right to be accepted. When some clue to details is given it can be inferred whether a contractor has special facilities for dealing with a particular class of work. The publication of ample information is also a boon to contractors as well as to architects and engineers. The following announcement of the tenders received by Messrs. Potter & Folwell, engineers, New

York, on December 20, for drainage work at West Pittston, Pa., is a model of above-board dealing:—

General conditions.—Character of digging:—Loam, average depth 6 feet, underlaid with gravel. No rock boulders or quicksand. Vitrified pipe, single strength up to 20-inch, remainder double strength. Brick sewers 8-inch work, inner ring to springing line laid in Portland cement. Concrete bottom in egg-shaped sewers. Right reserved to omit construction of any portion of the work. Monthly payments 85 per cent. Time of completion, July 1, 1895. McGarry & McGowan, Akron, O., \$36,459.72; Acocck & Son, Trenton, N. J., \$39,266.17; Ryan & Avery, Watertown, N. Y., \$39,553.17; A. Emonson, Carlisle, Ark., \$39,602.61; Headley & Christie, Newark, N. J., \$42,320.11; T. H. Ryan, North Tonawanda, N. Y., \$42,376.65; Corcoran & Connell, Pittsburg, Pa., \$43,022.47; W. Franklin, Buffalo, N. Y., \$43,319.63; A. W. Bryne, West Medford, Mass., \$44,531.35; Henry M. Dowd & Co., Orange, N. J., \$45,481.50; P. J. Cleary, Shenandoah, Pa., \$45,780.3; James McCloud & Co., Williamsport, Pa., \$46,160.90; Coon, Mooney & Co., Kingston, Pa., \$46,268; Sanders & Houston, Pittsburg, Pa., \$46,462.74; Lindsay & Van Loon, Plymouth, Pa., \$47,672.94; Dunn Brothers, Scranton, Pa., \$47,915.79; Hart & Gibbons, Wilkesbarre, Pa., \$51,152.46; Batton & Van Bussum, New York City, \$51,372.57; Brodhead & McConville, Scranton, Pa., \$54,350.3; R. CALCULATION OF WEIGHT OF IRON.*

BEAR in mind that a cubic foot of iron weighs 480 lbs., therefore an inch thick and foot square is 40 lbs., or one-twelfth of the cube foot. Therefore, also, half an inch equals 20 lbs., one-quarter inch equals 10 lbs., one-eighth inch equals 5 lbs., one-

sixteenth inch equals 2½ lbs., one-thirty-second inch equals 1½ lbs. You need not try to remember these, as by a quick mental process you can start with the foot or inch and in less time than it requires to write this, halve the inch, then halve the half inch, then the quarter and so on.

Now if your scantling be 3 inches by 1 inch, and as 1 inch a foot square is 40 lbs., the 3 inch bar will be one-quarter of 40 lbs., or 10 lbs. If your bar is 4 inches wide, or one-third of a foot, you will have one-third of 40 lbs., or 13½ lbs. For one-half inch bar, or one-quarter inch, or one-eighth inch, &c., the same process holds goods. For instance, a bar one-quarter inch thick and 2 inches wide will be the sixth part of a square foot, or the sixth part of 5 lbs., or five-sixths of a lb, since 5 lbs. by six thirty-sixths and thirty sixths divided by six gives five, or five-sixths lb., as just stated. Three inches by one-quarter inch will be one-quarter of 5 lbs., or 1¼ lbs., and so on.

Now take a bar 1 inch square, and since a foot inch is 40 lbs., the 1 inch bar will be one-twelfth of 40 lbs., or 3½ lbs., to the lineal foot. If the bar be 1 inch by 1½ inch, and as 1½ inch is one-eighth of a foot, the bar will weigh one-eighth of 40 lbs., or 5 lbs., since 8 into 40 gives 5 times. And if the bar be one-half inch by 1½ inch, it will be one-eighth of 20 lbs., or 2½ lbs. If the bar be 3 inches by one-quarter inch it will be one-quarter of 10 lbs., or 2½ lbs., and if one-eighth inch by 3 inches, 1¼ lbs., or the quarter of 5 lbs.

Say now your bar is seven-eighths inch square, and as an attempt to divide 12 inches or a foot by seven-eighths inch would lead to a more difficult or lengthy process, do it this way. Spread it over mentally into eighths of an inch. Thus seven times seven-eighths = 49 eighths, or 6½ inches in width of one-eighth inch thick iron. Now take for 6 inches (half a foot) the half of 5 lbs., or 2½ lbs., but there is still one-eighth inch by one-eighth unaccounted for, which, being only 1-48th of the 2½ lbs., may either be disregarded as a very small fraction of about 2 per cent.; or, if we wish to be more exact, and as it is mentally difficult, or even with pen or pencil, to get at the 48th part of 2½ lbs., reduce your 2½ lbs. to ounces, giving 40 ozs., and now you see that to the 2½ lbs. arrived at as above you have to add 0.83 of an ounce, or say four-fifths of an ounce, or even a whole ounce, as, except for hundreds or thousands of lineal feet, the neglected fraction of an ounce would hardly cover the trouble of exact computation.

Apply now the process to iron 1¼ inch square; reduce the bar in imagination to quarter-inch iron, when it will be 1¼ inches

SPRINKLER, Closed.

PROOF IMPRESSIONS of the BEAUTIFUL ART PLATES which appeared in the New Year's Double Number of "THE ARCHITECT," and in the Number for January 10, 1890, THE TOILERS OF THE DEEP. Two Tinted Ink Photographs (size 18½ in. by 13½ in.), may now be obtained. price 1s. each. Free by post, carefully packed in patent roller, 2s. 3d.—GILBERT WOOD & CO., 175 STRAND, LONDON, W.C.

by five times, or twenty-five quarters of an inch in width, or $6\frac{1}{4}$ inches, or half a foot plus one twenty-fourth of half a foot, and as quarter-inch iron weighs 10 lbs. to the foot, the 6-inch in width will give 5 lbs., and as 5 lbs. = 80 oz., and as the twenty-fourth part of 80 oz. is $3\frac{1}{2}$ (since three times 24 = 72 and 80 or $\frac{1}{4}$ oz. over), therefore to the aforesaid 5 lbs. add $3\frac{1}{2}$ oz., and the exact weight of the $1\frac{1}{4}$ -inch square bar per lineal foot is 5 lbs. $3\frac{1}{2}$ oz.

Again, if the square bar be $1\frac{1}{8}$ inch or 9-8 inch, and as nine times 9-8 = 81 eighths or $10\frac{1}{8}$ inch, and as 10 inches is the five-sixths of twelve, therefore the bar will weigh per lineal foot the five-sixths or 5 lbs. or of 80 oz. or 66 $\frac{2}{3}$ oz., but there still remains one-eighth inch to be accounted for, which just gives five-sixths oz. more, forming together 67 $\frac{1}{2}$ oz. or 4 lbs. $3\frac{1}{2}$ oz., say 4 $\frac{1}{4}$ lbs. nearly.

This last example may be more easily and quickly computed by taking the bar as so much of a foot of iron $1\frac{1}{8}$ inch thick, or 45 lbs. to the foot, when we get for 1 inch of it one-twelfth of 45 lbs., or $3\frac{3}{4}$ lbs., and for the one-eighth over add one-eighth of $3\frac{3}{4}$ lbs., or one-eighth of 60 oz. = 7 $\frac{1}{2}$ oz., together as before 4 lbs. $3\frac{1}{2}$ oz., or 4 $\frac{1}{4}$ lbs., nearly $3\frac{3}{4}$ lbs.

For computing the weight of sound bar-iron or of solid posts or columns of circular section, the simplest way is to compute as square and then reduce. Well, geometry teaches that the area of a circle is .7854 of its circumference scribing square, or that the area of any square is to be reduced to that of its inscribed circle by a multiplication of said area by the decimal fraction .7854, which is the area of a square of which the diameter is equal to one or unity. These figures .7854 will be better understood as a percentage. Thus, the area of the circle is very slightly in excess of 78 $\frac{1}{2}$ per cent. of its corresponding square. Now, since decimal 76 is equivalent to three-quarters, we therefore have to take, to begin with, three-quarters of the weight of our square bar, which is best and quickest done by taking half of it and then half of that, or a quarter of the whole. Now there still remain to be added 3 $\frac{1}{2}$ per cent. to get at the full weight required. This 3 $\frac{1}{2}$ per cent., or more, correctly $3\frac{5}{100}$ per cent., being multiplied by 7, we get (354 × 7) 2,478, or very nearly 25; therefore the remaining figures 354 of the .7854 are almost exactly equal to one-seventh of 25; therefore, by dividing the weight set opposite to the 25 per cent., or one-quarter of the weight of the square bar or scantling, we get the fraction to be added to the 75 per cent. already obtained to arrive at the comparative weight of the round scantling. Thus then we make unto our-

selves the rule:—To compute weight of round iron calculate it as square, and then take one-half, plus one-quarter, plus one-seventh of one-quarter of weight of square bar, this process being far shorter or more concise than that of multiplying by .7854, which would further require a reduction of the ounces or fractional portions of the weight to a decimal to allow of such multiplication.

Example.

Suppose the weight of one lineal foot of a bar of square iron to be 5 $\frac{1}{2}$ lbs. Thereby the rule, the corresponding weight of the round bar, or weight of a round bar of same size, will be the half of 5 $\frac{1}{2}$ plus the one-seventh of this last, or one-eighth × one-sixteenth or three-sixteenth lbs., together 4 $\frac{1}{10}$ lbs., or 2 $\frac{3}{4}$ lbs., plus the half of this or quarter of the whole, equal 1 $\frac{3}{8}$ lbs. or 4 lbs. 5 oz.

Otherwise, reducing the one-half lbs. to a decimal, we get 5.5 lbs. or reducing again the $\frac{1}{4}$ of which 2.75 " fraction of a lb. to decimals $\frac{1}{2}$ of this 1.375 " 5.5 lbs., and multiplying $\frac{1}{2}$ of this 0.1964 " by 7854

4.3214	39270
	39270
	431970

or 432 very nearly,

which shows that the fraction one-seventh for the remaining decimal 354 of the .7854 differs from it by little more than one-thousandth of a pound.

Now for cast-iron it is true the weight of a cubic foot is only 450 lbs. instead of 480 lbs. for wrought-iron; but as it is always safe in estimating in advance to be on the safe side to make up for any omitted trifling items, I generally use same figures as for wrought-iron; also because when contracted for by weight the tendency is to give the casting as great a weight as possible, and even when the thickness asked for is not exceeded there is generally a slight allowance to be made for so much of the sand or core adhering forcibly to the casting and hard of removal.

Therefore for any straight work or rectangular, as for a girder, column or stanchion of square, rectangular, crucial or cruciform or box-like cross section; estimating the elemental components and putting them together will give the weight or a lineal foot, which into the length or height of the column of girder will give its total weight.

WORKS, ROTHERHAM, Estab. 1854.

With regard to circular work, as of a cast-iron column, the inner diameter added to the thickness gives the mean diameter, and this taken $3\frac{1}{7}$ times gives the mean circumference or girth, which into the weight of a lineal foot of the column under consideration, and this last into the length in feet, will be the total weight of the column.

For example, say we have to compute the weight of a column of which the outer diameter is to be 8 inches and the metal $\frac{7}{8}$ inches thick, therefore the inner diameter or base will be $6\frac{1}{4}$ inches and the mean diameter $6\frac{1}{4}$ inches plus $\frac{7}{8}$ inches, or $7\frac{1}{8}$ inches (or which is the same thing, the mean diameter is similarly arrived at as the outer diameter, 8 inches, less the thickness of $\frac{7}{8}$ inch, equal $7\frac{1}{8}$ inches).

Now, diameter $7\frac{1}{8}$ inches by $3\frac{1}{7}$ gives 21 inches three-eighths by one-seventh of $7\frac{1}{8}$ inches, or say 1 inch; therefore mean circumference equals $22\frac{3}{8}$ inches, say $22\frac{1}{2}$ inches, or $1\frac{1}{4}$ feet superficial. Now, iron $\frac{3}{8}$ inch thick equals seven-eighths of 40 lbs. equals 35 lbs (or iron $\frac{1}{8}$ inch thick equals 5 lbs. and seven times 5 lbs. equals 35), and 35 lbs. into $1\frac{1}{4}$ times gives 65 lbs. for foot lineal.

If it be required to weigh any irregular form, such as a statue or piece of carving or scrollwork, of which the cubical contents are unknown, the latter may easily be had by immersion of the object in sand or water in a cylindrical or rectangular box or tub of quick and easy computation, and a mere comparison of the height when just covered by the sand or water with the height or depth of the auxiliary material after removal of the object. Thus, if the box be a foot square in cross section and the filling stand 3 feet high or deep with the object in it, and 2 feet 9 inches after the object is removed, the cubical contents arrived at are a foot square and 3 inches in height, or one-quarter of a cubic foot, or 120 lbs. If the object be hollow, it must of course be inverted in the bath, so the sand or water may fill the hollow space.

Or the weight of an object to be cast of any metal may be made known in advance by weighing the model of it in wood or any other material and by simple rule of three comparing their specific gravities. And in like manner, when the weight is known of any object, its cubic contents may be arrived at by a mere inversion of the terms of their proportion.

Thus of a shapeless piece of stone or wood or metal, the ratio of its cubical contents to those of a cubic foot of the material, from a table of specific gravities, will be the same as that of the weight of a cubic foot of the material to that of the piece to be computed.

In the foregoing mode of obtaining the cubical contents of an irregular figure by immersion in a vessel, if the vessel, instead of being cylindrical or rectangular, has tapering or splayed side, or be the frustum of a cone or pyramid, the contents must of course be computed by the prismoidal formula, which consists in adding to the sum of the areas of the upper and lower bases of the tub or vat four times the middle area (of which the factors are arithmetic means between those of the end areas), and multiplying the result by one-sixth part of the depth or height.

PATENTS.

[This List of Patents is compiled specially for this Journal by Mr. G. H. Rayner, of the firm of Rayner & Co., Consulting Patent Agents, 37 Chancery Lane, London, W.C., from whom all particulars and information relating to Patents may be had gratuitously.]

APPLICATIONS FOR PATENTS.

54. George Chisholme, jun., for "Improvements in and relating to sanitary pipes."

85. Edward Prew, for "Improved system and appliance for utilising the heat resulting from combustion which ascends the chimneys of buildings."

159. John Jones, Frederick Templar Farrer and William Walters Brown, for "Improvements in or relating to water waste preventers or flushing apparatus."

166. Frank Pullen Candy, for "Improvements in and in apparatus for use in or in connection with the purification of sewage or impure waters."

186. George Craig Brown, for "Improvements in and connected with windows."

205. Henry Baxter Worsey, for "Improvements in door-latches and latches for door-locks."

232. William Easun, for "Soil-pipe exhaust to draw the sewer-gas out of ventilating-pipe from drains and diffuse it."

233. George Burgum and George Burgum, jun., for "Window and casement-fastener."

TO INVENTORS.—Patents for Inventions, Trade-marks and Designs secured; every assistance given to inventors. Specialists in Building matters. Information free.—Messrs. RAYNER & Co., Patent Agents, 37 Chancery Lane, London, W.C.

WINTER, WARMTH AND COMFORT.

HEATING AND VENTILATING APPARATUS. GRUNDY'S SPECIALTY. PURE WARM AIR.

UPWARDS OF ONE THOUSAND TESTIMONIALS RECEIVED.

PURE WARM AIR AS SUPPLIED TO

Truro Cathedral; Londonderry Cathedral; Sherborne Abbey; Kilmore Cathedral; Stanley Cathedral, Falkland Islands; Cardiff Catholic Cathedral; the Queen's School Chapel, Eton; Cork Asylum; Leicester Asylum; and to upwards of three thousand Places of Worship; and a great number of Mansions, Houses, Hotels, Hospitals, Schools, Warehouses, Factories, Workhouses; Cork Law Courts, &c., &c.

84 Brook Street, Grosvenor Square, W.: December 8, 1893.

Sir WILLIAM BROADBENT encloses cheque for the "GRUNDY" HEATING APPARATUS supplied to his house, and is glad to say that it has proved very satisfactory for warming and ventilating as required. The principle of the apparatus is most excellent.

To Mr. Grundy.

PROFESSOR TYNDALL writes:—

Dear Sir,—My house being so well provided with grates and flues for the generation and distribution of pure warm air, I have been thus enabled to spend my winters in England instead of on a foreign shore.—Yours very truly,

October 24, 1893: Hind Head House, Haslemere.

JOHN TYNDALL.

Fever Hospital and House of Recovery, Cork Street, Dublin: October 26, 1894.

Dear Sir,—I have much pleasure in informing you that we have found your HEATING APPARATUS a great success in our new Epidemic Hospital, which consists of a two-storey building, each storey containing two large wards, a smaller isolation ward, and two nurses' rooms. It is easily managed, does not cost much for fuel, and the air entering is most pleasant, warm, and free from smell. It is with the full concurrence of the Managing Committee I give you this testimonial.

Yours faithfully, JOHN MARSHALL DAY, Registrar and Resident Medical Officer.

THE
Architect and Contract Reporter.

NEW READING CASE.

To Librarians of the Public Libraries and Reading-rooms.—A new handsome Reading Case can be supplied at a nominal charge of 2s., by post 2s. 6d., on early application to the Publisher, 175 Strand, W.C.

SPECIAL NOTICE TO THE TRADE AND OTHERS.

[Extract from a lecture on Architects' Libraries by Professor T. Roger Smith, F.R.I.B.A., at University College, October 10, 1893.]

"Lastly, let me recommend the back volumes of the professional journals. In the course of years all sorts of architectural topics come up in the public press and before the professional societies, and if you hunt through the indexes of these publications when you are seeking for information which eludes you in books, you will often be rewarded."

There has been a considerable demand for the back numbers of *The Architect* during the last three or four months, which we have no doubt has arisen from the remarks made by Professor Roger Smith, as contained in the above quotation; but the consequence has been that our stock of back numbers is getting very low, and consequently, in future, the charge for back numbers of previous date to January 12, 1894, will be 6d. each.

A few of the back volumes may still be had, price 12s. each.

EDITORIAL NOTICES.

The authors of signed articles and papers read in public must necessarily be held responsible for their contents.

No communication can be inserted unless authenticated by the name and address of the writer—not in every case for publication, but as a guarantee of good faith.

Correspondents are requested as much as possible to make their communications brief. The space we can devote to Correspondence will not usually permit our inserting lengthy communications.

COMPETITIONS OPEN.

DURHAM.—March 25.—Competitive Schemes are Invited for the Sewage Disposal of the District. Premiums 100l. and 50l. for Two Best Schemes. Mr. F. Marshall, Town Clerk, Durham.

IPSWICH.—March 25.—Designs are Invited for the Building of a Workhouse and Infirmary, with Specifications and Estimate. Premiums 100l. and 50l. Mr. A. F. Vulliamy, Clerk to the Guardians.

LEEK.—March 4.—Designs are Invited for Proposed Covered Markets. Premiums 50l., 25l. and 10l. offered. Right reserved to carry out the Work by the Board's Architect. Mr. C. Henshaw, Clerk to the Improvement Commissioners, Leek.

CONTRACTS OPEN.

ASTON-CUM-AUGHTON.—Feb. 5.—For Building Teacher's Residence at Board School. Mr. F. Leonard Sorby, Architect, Todwick, near Sheffield.

BANDON.—Jan. 30.—For Additional Works for Water Supply. Mr. A. Haynes, Executive Sanitary Officer, Bandon, Ireland.

BANGOR.—Feb. 2.—For Building Baptist Chapel at Glanadda. Mr. R. Glynne Davies, Architect, 220 High Street, Bangor.

BATH.—Jan. 26.—For Additions to Lyncombe Schools. Mr. C. Bryan Oliver, Alfred Street, Bath.

BATLEY.—Jan. 28.—For Building Six Terrace Houses, Outbuildings and Boundary Walls. Mr. J. H. Brearley, Architect, Commercial Street, Batley.

BEAUMARIS.—Jan. 29.—For Additions to County School Premises. Mr. Evan Thomas, Borough Surveyor, Beaumaris.

BELFAST.—Jan. 25.—For Stabling at Musgrave Street Constabulary Barracks. Mr. P. J. Tuohy, Secretary, Office of Public Works, Dublin.

BEXLEY.—Jan. 30.—For Supply of Materials for One Year from March 25. Mr. Z. Reeve Boulter, Council Offices, Bexley.

BIDEFORD.—Jan. 31.—For Building Premises for Messrs. Tattersill & Snow. Mr. R. T. Hookway, Architect, Bridgeland Street, Bideford.

BILSTON.—Feb. 9.—For the Construction of Engine-house, Boiler-house, Well-house, Workshop, Coal Shed, Chimney Shaft, Entrance Gates, Fencing, Road-making, &c. Mr. Baldwin Latham, M.I.C.E., 13 Victoria Street, S.W.

BOOTLE.—Jan. 29.—For Steps with Balusters and Retaining-Walls for Terrace in the New Park. The Borough Surveyor.

BROMLEY ST. LEONARD.—Jan. 28.—For Converting Church Institute into Branch Public Library. (Firms in Bromley, Bow or Poplar to tender.) Mr. C. Stanley Peach, Architect, 8 John Street, Adelphi.

BOURNEMOUTH.—Feb. 9.—For Erection of Show Building and Works in Connection with the Royal Counties Agricultural Society. Mr. Charles Simmons, Basingstoke.

VERITY BROS. CALL LANE, LEEDS.

Manufacturers of their High-Class

ROLLING BOLT, MORTICE & RIM LOCKS, NIGHT LATCHES, &c.

In our Deadweight Lock as per drawing herewith, we have so applied the different Movements that the pressure is equal in both ways of turning the knob, and we guarantee their giving entire satisfaction

We are also Manufacturers of—

The largest Varieties of Openers suitable for Skylights, Fanlights, &c., which can be fixed in any position.

Casements in Wrought Iron, Steel, and Gun Metal.

Espagnolette Bolts, Weather Bars, Sash Fasteners, Door Checks.

CATALOGUES FREE BY POST.

BOURNEMOUTH.—For Building Infant School and Other Additions, for the British School Committee. Messrs. Lawson & Donkin, Architects, Yelverton Chambers, Bournemouth.

BRIDGEND.—Jan. 31.—For Building Detached Villa. Messrs. Lambert & Rees, Architects, Bridgend.

BRYMBO.—Feb. 7.—For Additions to the Vron Schools. Mr. W. Moss, Architect, Belgrave Cottage, New Broughton.

CANTERBURY.—Feb. 2.—For Pulling-down Old Premises, St. Radigund's Street, and Building Four Cottages. Mr. W. J. Jennings, Architect, 4 St. Margaret Street, Canterbury.

CARLISLE.—Feb. 11.—For Building House for Private Patients at the Lunatic Asylum. Mr. G. D. Oliver, Architect, Carlisle.

CHELSEA.—Jan. 31.—For the Supply and Execution of Various Articles and Works for a Period of One Year. Mr. T. W. E. Higgins, Surveyor, Town Hall, King's Road, S.W.

CITY OF LONDON.—Jan. 25.—For Construction of Sewer Subway, &c., in Sandy's Row. Engineer, Sewers Offices, Guildhall.

CLONES.—Feb. 4.—For Carrying-out Waterworks. Mr. J. H. H. Swiney, Engineer, Avenue Chambers, Belfast.

COSHAM, HANTS.—Jan. 29.—For the Execution of Outfall Sewage Works. Mr. Graham Whitlock, 97 West Street, Fareham.

CROYDON.—Jan. 28.—For Erection of Boundary Walls at the Infirmary in Mayday Road. Mr. Frederick West, 23 Coombe Road, Croydon.

DEWSBURY.—Jan. 28.—For Rebuilding the George Hotel. Mr. W. H. D. Hersfall, Architect, 9 Harrison Road, Halifax.

DOWNTON.—For Building Board Schools, Board Room and Boundary Walls. Messrs. John Harding & Sons, Architects, 51 Canal, Salisbury.

DUNGARVAN.—Jan. 31.—For Works of Building, &c., at Bathing Place. Mr. Thomas M'Carthy, Town Clerk.

FARNHAM.—Jan. 28.—For Erection of Board Schools and Teachers' Residences. Mr. J. Alfred Eggar, Architect, Farnham.

FARNHAM.—Feb. 5.—For Additions to Wrecchlesham Schools. Mr. W. J. Wells, Architect, West Street, Farnham.

FULHAM.—Jan. 30.—For Making-up and Paving Bedford Place. Mr. Chas. Botterill, Town Hall, Walham Green, S.W.

GODALMING.—Feb. 14.—For Building Cemetery Chapels, Lodge and other Works. Messrs. Welman & Street, Church Street, Godalming.

HARROGATE.—For Building Board School. Mr. T. Edward Marshall, Architect, Prince's Street, Harrogate.

HASLINGDEN.—Feb. 16.—For Construction of the following Lengths of Brick Sewers, viz. 1,213 Lineal Yards 3 feet 4 inches Diameter Sewer in 9-inch Brickwork; 1,628 Lineal Yards, 3 feet 6 inches by 2 feet 4 inches in 9-inch Brickwork; 25 Lineal Yards 3 feet Barrel Overflow Sewer in 9-inch Brickwork—2,866 Lineal Yards. Together with Bell-mouth Junction, Overflow and Penstock Chambers, Manholes, and other Works in Connection therewith. Mr. Henry A. Cutler, A.M.I.C.E., Municipal Offices, Rawtonstall.

HASTINGS.—Jan. 29.—For Laying Sewers. Mr. A. R. Inskip, 11 Wellington Square, Hastings.

HAVANT.—Jan. 30.—For Building Classroom and Offices at Board School, Bedhampton. Mr. G. C. Vernon Inkpen, Architect, 6 King's Road, Southsea.

HUDDERSFIELD.—Jan. 31.—For Additions to Meltham Hall. Messrs. John Kirk & Sons, Architects, Huddersfield.

HULL.—Jan. 29.—For Building Shops, Houses, &c. Mr. H. W. Ward, Recorder Office, Beverley.

ISLINGTON.—Jan. 28.—For Paving with Wood Blocks the Carriage-way in Highbury Grove. Mr. J. Patten Barber, Vestry Hall, Upper Street, N.

KEGWORTH.—Jan. 31.—For Building Factory, with Store-rooms, &c. Mr. George H. Barrowcliff, Architect, Loughborough.

KELTY.—Jan. 30.—For Building Premises, Bakery, &c., at Oakfield. Mr. John Houston, Architect, St. Margaret Street, Dunfermline.

KENDAL.—Feb. 4.—For Building Two Pairs of Semi-Detached Houses. Mr. John Stalker, Architect, 57 Highgate, Kendal.

LAUNCESTON.—For Additions to Bolventor School, Altarnum. Messrs. Wise & Wise, Architects, Launceston.

LEEDS.—Jan. 28.—For Reconstructing Roof Lights at Covered Market and Repairing with Durolite Skylights at Victoria Cattle Market. The City Engineer.

LITTLE BADDOW.—Feb. 1.—For Additions to National Schools. Mr. Charles Pertwee, Architect, Chelmsford.

TRADE NOTES.

WE have much pleasure in announcing that Messrs. Isaac Dixon & Co., of Liverpool, have just completed an iron hospital for the Wirral Joint Hospital committee at Clatterbridge, Cheshire.

THE new Board Schools, Aspatia, are being warmed and ventilated by means of Shorland's patent Manchester grates, inlet tubes, &c., the same being supplied by Messrs. E. H. Shorland & Brother, of Manchester.

AT the meeting of the Glasgow Bridge Committee, the offer of Messrs. Morrison & Mason, Limited, to take down the existing bridge over the Clyde at Jamaica Street and to erect a new bridge of British granite for 81,175*l.* 5*s.* was definitely settled, and the work will now be proceeded with without delay.

THE Local Government Board have sanctioned a loan of between 11,000*l.* and 12,000*l.* for the purchase by the Belper Local Board of the undertaking of the Belper Waterworks Company, and the works are to be extended.

THE London postal address of Messrs. Joseph Robinson & Co., Limited, of London and Carlisle, plaster and cement manufacturers, is 206 Phoenix Street, St. Pancras, N.W. One of their special manufactures is Robinson's simplex fire and sound-proof partition blocks. We have before now explained the merits of this system for walls, &c., as a protection in case of fire and preventing the transmission of sound, as a very reliable system, economical, and effecting much saving in time and labour. Another merit is found in its application to metal-work.

STEEL-MAKING is to be restarted at Glengarnock Steel Works, Glasgow, and the necessary works for putting the plant in order are being carried out.

BUILDING AND BUILDERS.

A TECHNICAL Institute is about to be erected in St. James's Road, Kingston-on-Thames, at a cost of about 4,000*l.*

AT the meeting of the Aston Board of Guardians the building committee reported that they had discussed the conditions, already approved by the Board, for the invitation of plans for the proposed Cottage Homes. They recommended that the conditions be permitted to stand, subject to the following alterations:—That the cottages to be erected should be four to accommodate 30 children each, six to accommodate 24 children each, and two to accommodate 16 children each; that the infirmary be made to accommodate 24 children (12 boys and 12 girls); that a general laundry be provided, and a washhouse to each of the girls' homes; that the entrance be in Fentham Road, and that the Guardians shall have the option of employing the successful competitor as their architect, or of awarding him the sum of 70*l.* for his plans, which should become the property of the Guardians. The report was adopted.

ALLUDING to the railway extension, the *Nottingham Guardian* says buildings in Nottingham are being taken down, including the old Town Hall and premises in Trent Street, on the Queen's Road, in Waterway Street, Kirke White Street, &c. The number of visitors to the dungeons beneath the old Town Hall has been very large, and great interest has been taken in the building and all it contained. Local and distant lovers of antiquities have purchased many souvenirs—all the dungeon doors have been sold, wax impres-

Complete Installations for Central Lighting Stations.

Also for Public Buildings, Mills, Workshops, Mines, &c., including Steam Boilers, High-speed Engines with Automatic Expansion Gear, Dynamos and Fittings of Improved Design.

SALFORD IRONWORKS, MANCHESTER.

London Office: 16 VICTORIA ST., WESTMINSTER.

D. HULETT & CO. LIMITED.

ELECTRIC LIGHT ENGINEERS

AND FITTINGS MANUFACTURERS.

Estimates submitted for Complete Installations. Large Staff of Competent Workmen under experienced supervision.

GASFITTERS AND HOT-WATER ENGINEERS.

ESTIMATES GIVEN FOR EVERY DESCRIPTION OF GAS LIGHTING AND HOT-WATER APPLIANCES.

ELECTRIC BELL AND SPEAKING-TUBE FITTERS.

Gasfitting Manufacturers, Chandeliers, Brackets, Hall Lights, &c.

SHOWROOMS AND MANUFACTORY:—

55 and 56 HIGH HOLBORN, LONDON.

sions of the crowd of initials and names carved upon the stone found in the debtors' cell have been taken, and a brisk business has been done in walking-sticks and other articles fashioned from the oak about the place. All the walls are now down, and very soon no trace of the historical spot will be left at Weekday Cross. A temporary wooden bridge crosses the Trent, though not on the line along which the viaduct will be constructed, and temporary rails are laid to Wilford.

At the annual meeting of the Manchester and Salford Builders' Association just held, it was reported that notices for revision of rules, shortening the hours of labour, increase in rate of wages per hour, &c., had been received from all the branches of labour in the building trades in the neighbourhood, and a committee was appointed to look into the various communications received and report thereon. Mr. Robert Neill, jun., of Manchester, was elected president of the Association for the ensuing year.

THE Albion Saw Mills at West Hartlepool have been destroyed by fire. Large quantities of manufactured timber were consumed, the damage being estimated at about 6,000*l*.

ELECTRICAL.

In distributing the prizes at the Crewe Mechanics' Institute on Friday last Lord Kelvin said that, in going through the Crewe works that day, he was much struck with the new electrical development which was taking place. He himself took an intense interest in electricity early in life, and he had never ceased to take an interest in it. He did not predict that it would come to pass immediately, but he thought it possible that steam locomotion might be superseded on their railways by electricity.

THE Worcestershire Council have confirmed a contract with Messrs. Verity for the supply of fittings, amounting to 91*l*. 3*s*. 11*d*., in connection with electric lighting of the Shire Hall. The question of confirming a contract with the New British Electric Installation Company, for 474*l*. 6*s*. 6*d*. for wiring the building, was allowed to stand over.

THE inhabitants of Adelaide have been polled to decide whether the city should be lighted by gas or electricity. The result of the polling was 3,382 votes in favour of gas and 2,255 for electricity.

At the meeting of the Coventry City Council a report was submitted by the electric-light committee:—In order to be in a position to let meters on hire to consumers your committee advertised for tenders for the supply of meters of various sizes, according to a specification prepared by Mr. Hammond, their consulting engineer. The following tenders were received, the price stated in each case being for the sixty meters which it is proposed to procure in the first instance:—Chamberlain & Hookham, Limited, Birmingham, 270*l*. 10*s*.; Westinghouse Electric Company, London, 295*l*. 17*s*. 9*d*.; Electric Construction Company, Limited, Wolverhampton, 299*l*. 4*s*.; General Electric Company, Limited, London, 336*l*. 7*s*. 6*d*.; British Thomson-Houston Company, Limited, London, 406*l*. 5*s*. 4*d*.; Charles A. Miller, Bradford, 462*l*.

THE Mayor of Tunbridge Wells is an amateur electrician of great experience and ability, and can show at Broomhall, his luxurious residence in that town, one of the most perfect electrical installations in the country.

To prevent underground electric explosions it is suggested that ventilation is only required to insure perfect immunity from such explosions, and that further to obviate the trouble of opening traps it will be sufficient to have the trap-doors perforated.

THE special lighting committee of the Liverpool Corporation have decided to recommend the Council to consider, and if thought expedient to approve of the intention to apply to the Board of Trade for a license to supply the city with electricity for public and private purposes.

VARIETIES.

AN inquiry has been held by the Local Government Board as to an application from the Macclesfield Town Council for a loan of 60,000*l*. for sewerage and sewage disposal. Mr. W. H. Radford, of Nottingham, is the engineer.

At the ordinary meeting of the Civil and Mechanical Engineers' Society, on Thursday, January 17, a paper was read by Mr. A. Hanssen, C.E., on "Checking Engineering Calculations." In it he dealt with the necessity of systematically carrying out the work and the advantages of using mechanical aids, more particularly alluding to the slide rule, calculating machines and various forms of planimeters. A discussion ensued, and after the usual vote of thanks to the author the meeting was adjourned.

THE MOST PERFECT AND RELIABLE SYSTEM OF

VENTILATION AND HEATING FOR SCHOOLS, AND EVERY CLASS OF BUILDING.

The air of Class-rooms renewed every six minutes in all weathers positively and without draughts, no foul air anywhere; for a school of 1,000 68 tons weight of air impelled into it every hour. All buildings ventilated and warmed mechanically. No failures nor breakdowns.

Estimates on Shortest Notice.

Low Working Expenses.

WILLIAM KEY, Ventilating and Heating Engineer, Central Chambers, 109 Hope Street, GLASGOW.

W. DUFFY'S PATENT IMMOVABLE ACME WOOD BLOCK FLOORING.

THE PERFECT FLOORING FOR ALL PURPOSES.

Seven Gold Medals, four Silver, two Bronze Medals, and Certificate of Sanitary Institute of Great Britain.

Full Particulars and Prices on application to

THE ACME WOOD FLOORING COMPANY, Ltd.,

Chief Office and Works:—Vauxhall Walk and Glasshouse Street, London, S.E.

PROOF IMPRESSIONS of the BEAUTIFUL ART PLATES which appeared in the New Year's Double Number of "THE ARCHITECT," and in the Number for January 10, 1890, THE TOILERS OF THE DEEP. Two Tinted Ink Photographs (size 18½ in. by 13½ in.), may now be obtained, price 1*s*. each. Free by post, carefully packed in patent roller, 2*s*. 3*d*.

GILBERT WOOD & CO., 175 STRAND, LONDON, W.C.

AT the meeting of the markets and fairs committee, it was announced that the Local Government Board had given the Birmingham Corporation power to borrow the additional 5,000*l.* required for the new meat market, without any further inquiry by the Board.

A VOLUNTEER fire brigade has been organised for Toxteth Park Township, Liverpool, by Mr. John Price, the district engineer. The engine supplied by Messrs. Merryweather & Sons is of light "County Council" pattern, capable of delivering 200 gallons of water per minute and of throwing a single jet to a height of 140 feet, or as many as four jets may be used simultaneously. The boiler is Merryweathers' patent quick steam raising type, fitted with curved and inclined tubes, and an annular water casing surrounding fire-box. Steam can be raised from cold water in four minutes, and to full working pressure in from six to eight minutes from time of lighting the fire.

THE Melbourne Builders and Contractors' Association have appointed a committee to consider the condition of the Exchange, which has ceased to pay, and is used by many men who never pay one farthing towards the expenses of conducting it. There are other exchanges which are not profitable concerns.

ANTHYDOR PAINTS.

WE are pleased to hear that what is known as the "Anthydor" compound has found so much favour as an excellent substitute for oil paints and distemper. For inside or outside use it can be had washable or not, as ordered. Among other advantages it possesses, it may be stated that it does not become discoloured as some compounds do, owing to changes resulting from the admixture of chemical agents. In many cases, especially in outside work, the washable Anthydor is most useful as proof against weather and elements. In another form the compound can be removed without much difficulty if required. The company also claim that, manufactured by a new process and of the best materials, it has proved a success in beauty, colour, covering properties and durability; also that these compounds are absolutely lime-resisting, easily applied on any paper, inside and outside walls of all kinds, woodwork, iron, &c., that it requires nothing added but tepid water to thin it down to the consistency of cream, and can be applied with either distemper or paint brushes, which it will not injure. It works like paint, and woodwork requires no special preparation

beforehand. It is cheaper than wall-papers, dries smooth and bright, keeps its colour, and is most effective for high-class decorative work. The address of the company is 47 Victoria Street, S.W., Mr. Waller, secretary and manager.

A NON-POLARISING BATTERY.

A DISCOVERY of great importance connected with the production and utilisation of electricity has recently been effected in Birmingham, and is exciting much interest and discussion amongst electricians and other scientists. For many years—in fact, ever since electricity has become one of the applied sciences—the problem which has most occupied the thoughts of electricians has been how to produce a primary voltaic cell which will give a continuous current of electricity without polarisation. This much-desired object, says the *Daily Post*, we understand has at length been accomplished by two Birmingham electricians, Messrs. William Walker and Frank Wilkins, who after several years of research and experiment have succeeded in producing a non-polarising voltaic battery, consisting of one or more simple primary cells or chemical generators of electricity. The unique feature of this invention is that by an ingenious use of the atmosphere the electric current in the cell is kept perfectly steady, the action of the hydrogen on the negative element or carbon being neutralised by the oxygen, and polarisation consequently prevented. Hitherto, in order to maintain the pressure, costly chemicals had been used, which made the cost of the electric current produced far too expensive for practical or general use, and at the same time the current has not been trustworthy for more than a few hours together. It has been demonstrated that by the use of the new patent voltaic battery no less than 97 per cent. of the zinc used is given back in electricity, compared with only about 40 per cent. under the ordinary processes, whilst the pressure of the electric current is maintained throughout until its complete exhaustion, when it can be easily replenished. The voltaic cell is composed of an amalgamated split cylinder of zinc, immersed in a solution of caustic potash, contained in a porous pot placed concentrically within a larger perforated outer vessel. The space between these vessels is packed with carbon, the carbon in contact with the porous pot being powdered, while that next the outer vessel is granular. The current is collected by means of a perforated metal cylinder embedded in the granular carbon. The advantages claimed

for the cell are freedom from offensive or obnoxious fumes when working, the simplicity of the cell and of the charging solution, and the almost entire absence of local action and unnecessary waste of zinc. The uses to which this invention can be applied are innumerable, and it will probably not only revolutionise the present system of domestic lighting by gas, but also become a valuable motive power in connection with many of the light mechanical and fancy industries throughout the world. In addition it will be found of the greatest utility in the lighting of country railway stations, railway carriages, signals, telegraphy, mining lamps and mining purposes. As a motor it will be especially welcomed by users of power, from the smallest possible work, such as a dentist's drill, up to 2 or 3 horse-power, and it will, therefore, be available for small manufacturers in the jewellery, electro-plate, leather and other fancy trades, who are unable through want of means or space to put down steam or gas-engines and the necessary electrical apparatus, and who have consequently to hire the use of machinery at other establishments. It is anticipated, therefore, that the new motor will practically transform the lighter trades of Birmingham, Sheffield and other towns both at home and abroad. The invention can also be used economically and successfully in the printing and bookbinding trades, in the boot, woollen, silk and cycle industries, and particularly for driving fans for ventilating unhealthy workshops, basements of hotels, the lighting and ventilating of ships, and for driving propellers of pleasure-boats. The invention will also be found exceedingly useful for domestic purposes, such as the driving of sewing machines, enabling many comforts to be provided hitherto unattainable by the general public, as it will be a generator of power without offensive odour, noise, or the employment of expensive machinery and labour, with an entire absence of wear and tear and waste of material when not at work. It is not intended that the new electric generator shall be brought into direct competition with gas-lighting in towns and districts where public lighting is effectively carried out; but it will enable the dweller in country districts where no such supply is available to provide his own electric illumination at a comparatively small expense, as this system dispenses with the necessity of the costly machinery necessary to work the dynamo. It is anticipated, however, that this method of lighting will be found to be infinitely preferable to gas from the point of view of ventilation, and that it will eventually be adopted by many householders, both large and small, on general sanitary considerations. At present the cost of laying

down an electrical installation is so expensive that it can only be effected with advantage by the owners of large establishments, whereas the new system can be brought within the reach of all, the arrangement for utilising the light being of the simplest possible character. Hitherto separate and private installations of the electric light have only been provided by putting down a steam-engine with dynamo and accumulators, whilst with the Walker-Wilkins patent the installations can be supplied for the mere cost of the accumulators. Users of these voltaic batteries will further derive a great advantage in the sense of economical consumption by having the manufacturing and consuming apparatus under their own personal control.

In the early stages of the discovery, the inventors consulted Mr. Jabez Lones, of the firm of Messrs. Lones, Vernon & Holden, of the Sandwell Iron and Axle Works, Smethwick, as to the best methods of utilising the invention for commercial purposes, and that gentleman, after consultation with a leading local patent agent, was convinced that the invention was both novel and new to the electrical world. Thereupon an influential syndicate was formed taking over the cost of patents, preliminary experiments, and the obtaining of the scientific opinion of eminent electrical experts. Professor Jamieson, M.I.C.E., F.R.S.E., of Glasgow, one of the highest electrical authorities in the country, has made an exhaustive investigation and analysis of the patent, and states that this "non-polarising cell is the best of its kind I have ever tested;" and expresses the belief that "it will prove very serviceable for driving electric motors, for electric lighting, and for the electro deposition of metals where engines and dynamos are not available." In his report Professor Jamieson gives the results of a number of potential current tests, showing the efficiency of the voltaic cells as generators of electrical energy, and further reports that he considers them "symmetrical in form, substantial in every detail, and thoroughly well made." Patents have been secured for the United Kingdom, and the invention has also been patented on the Continent of Europe, in the United States of America, and most of the civilised countries of the world. It is the intention of the syndicate, in the first place, to offer the sale of their patents to corporations and local authorities who are manufacturers of gas and to gas companies, enabling them to undertake domestic lighting. For the multitudinous purposes for which the invention can be used as a motor it is proposed to offer the manufacture, sale and use to local electrical companies supplying electric motors in our cities and towns.

HEWETSONS, Tottenham LONDON, W.

HOUSE FURNISHERS & DECORATORS,

Extract from THE GENTLEWOMAN (Mrs. PANTON).—"You can find all the furniture at Hewetsons', or if you are dubious of your own powers, you could either send me the pretty catalogue to mark, or my daughter could choose them next time she is in town, if you liked. The catalogue should certainly be seen; it is entirely a work of art, and most useful to country residents."

PATENT TILES.

WE have recently inspected the works of the Self Lock Roofing Tile Company. This is a system that should be inspected by all who have, or intend to, undertake building operations, more especially as it has commended itself in countries where the weather is more stormy than here. The Americans are credited with saying that in England we have only samples of weather. The truth proposed to be conveyed by that assertion means that having no long continuous state of weather, hot or cold, wet or dry, stormy or calm, we are never able to provide properly for any contingency. regard to this system of roof, we need only refer to its capability as to artistic effect and say that the materials employed, combined with the method of manufacture, produce the most durable of roof-tiling. Independently of the above-mentioned features, the tiles carry in themselves constructive details that secure a solid fixing without extra assistance of any

are practically imperishable, and they better with age and weathering. Another recommendation is that any single tile can be removed at any time and replaced without disturbing those beside it.

The tiles can be manufactured anywhere, and the company propose, instead of erecting large works in London, to make

FRONT VIEW OF WHOLE TILE.

REVERSE VIEW OF WHOLE TILE.

kind, whether nails, pegs, &c., and also require no boarding to support them. The roof thus formed may be said to be as solid as rock. It is at the same time very light, and it seems absolutely impossible that in the most exposed situations rain, snow, sand, or wind can penetrate. This may be expected on examining what we have called the constructive features of the tiles. At the same time, under ordinary conditions of calm weather there is circulation of air, which is another welcome advantage. Owing to the nature of the materials used the tiles

are practically imperishable, and they better with age and weathering. Another recommendation is that any single tile can be removed at any time and replaced without disturbing those beside it.

The tiles were recently put under a severe test by a well-known architect, who was so pleased with the result that he specified them at once for an important building which will shortly be commenced.

TECHNICAL EDUCATION.

AT the first annual general meeting of the Association of Technical Institutions Mr. W. Mather, M.P., was elected president for the ensuing year.

The President, in his address, said he understood the object of the Association to be to afford the means of intercommunication between those who were responsible for the organisation and management of technical schools and colleges, by which opportunities might be provided by the friendly interchange of ideas between persons engaged in similar work in different parts of the country. He was one of a considerable number of employers engaged in conducting some of the great industries of this country, who had foreseen a great national danger in our general indifference to the absence of systematic scientific instruction in the industrial training of young people, and who had during the last fifteen years or more tried to promote schools of industrial science as a basis for their manufactures, arts and commerce in the future. The local authorities of England and Wales received about 780,000*l.* per annum from the duty on whisky and beer. They allotted in 1893-94 654,000*l.* to educational purposes. Of this 73,000*l.* was last year applied by 37 councils to agricultural education. The returns of 1894-95 showed that out of a total of 110 counties and county boroughs in England 96 were giving the whole and 13 part of their grants to educational purposes. In London, though only tardy progress had been made, probably the whole of the grant would be bestowed very shortly—namely, 171,000*l.*—for educational purposes. There would probably remain only about 30,000*l.* of the total sum of 780,000*l.* devoted to the relief of local rates after this year, and the few local authorities who used the money for this purpose would, it was to be hoped, follow the lead of the country generally before long and devote it to technical education. The provisions of the Technical Instruction Acts were being utilised by at least 138 local authorities who had levied part of their permissive penny rate to maintain schools and in some cases to raise loans to build technical schools. Upwards of 200 technical schools are now at work in Great Britain. So far as the pecuniary facilities conferred by the Acts were concerned, the position might be stated as follows:—They had in grants and optional rates the means of annually bestowing on technical education in England and Wales (1) from grants under the Local Taxation Act about 780,000*l.*; (2) from the local penny rate in England and Wales to be derived from county

boroughs, other boroughs and local boards, but exclusive of rural sanitary authorities to which the Technical Instruction Act did not apply, about 271,000*l.* This last mentioned sum was equal to a capital sum of about 5,500,000*l.*, repayable over forty years. But under the District and Parish Councils Act the rural sanitary authority had vanished and the penny rate might be levied by the new bodies which covered the whole country. A penny rate levied now would yield on the total rateable value of the whole country, which was 160,000,000*l.*, a sum of 664,500*l.* per annum; and supposing the rate to be made compulsory under a great scheme of secondary education, a capital sum of about 14,000,000*l.* could be raised, repayable by the rate in forty years. A third source of revenue for technical education came from the grants of the Science and Art Department for science and art classes, and amounted to about 355,000*l.* Adding this to the two former, they got a total of about 1,406,000*l.*; or if they took in the whole country, including the rural districts, the total would be about 1,800,000*l.* To these sums there was further to be added the voluntary aid to technical institutions, happily growing, in which they had to include some of the highest colleges. This movement now urgently demanded guidance, consolidation and organisation to maintain its permanent strength and continuity. The blending of brain, hand and eye in all the work of the primary school was the chief want to-day in our public school method of teaching.

IMPROVED METHODS OF HOUSE-DRAINAGE IN AMERICA.*

YOUR committee has honoured me with an invitation to prepare a paper for this meeting, and has left me entirely free to select some topic from the wide and constantly growing field of sanitary engineering. The sanitation of houses, school hygiene, hospital construction, rain-baths, domestic gas-lighting, the sanitary features of the laying out of cities, water-supply, fire-prevention and fire-extinction, the safety in theatres and halls of amusement—these were some of the numerous subjects which occurred to me as being of interest to the members of the Architectural League.

* A paper read at the monthly meeting (December 5, 1894) of the Architectural League, by Wm. Paul Gerhard, C.E., consulting engineer for sanitary works.

NATIONAL TELEPHONE No. 6.

Telegrams, "IRON, WELLINGBORO'."

After thinking the matter over for some time I concluded that it would be better to select a subject in which I have been most actively engaged in the past years. Accordingly I decided to speak to you on "Improved Methods of House-Drainage," although I was well aware of the fact that I could not attempt to treat the matter from any novel point of view. For while the subject is of paramount importance and one in which every architect takes an interest, it has been quite frequently discussed, and there are numerous books, pamphlets, essays and lectures which go into the matter very fully.

I can, therefore, assure you that it is with the utmost diffidence that I come before you to-night to give a brief address on what many of you will doubtless consider a dry and uninteresting subject.

My endeavour will be to explain some important improvements which have been brought about in the past ten years in the art of draining houses.

To begin with, one quite noticeable improvement relates to drainage plans. Until a comparatively recent period of time, it was an exception to find elaborate plans and sections of the plumbing and drainage system of buildings. The location of the plumbing fixtures was, to be sure, indicated on the floor plans of the building. Beyond this, very little information was given. It was not usual to mark the number and sizes of soil-pipe stacks, neither was the run and course of the drains indicated on the plans. I believe I am not mistaken in stating that in architects' offices the practice of making a special drainage plan began with the enactment of the plumbing laws. At least, I remember distinctly that, when as chief engineer of a house-drainage company it was my privilege, about ten years ago, to estimate in some of the prominent architectural offices in this and in other cities, I was given plans to estimate on where the drains and soil-pipes were neither shown, nor enumerated or described in the specifications. All this has undergone a great change in the past few years.

Owners of buildings are much benefited by the plumbing laws which require plumbing plans to be filed in the City Health or Building Departments. Even where in the actual construction of the work the drainage plan is, more or less, modified, there is kept on record a usually tolerably accurate plan, showing the position of pipes, in case of future reference. In important cases a revised drainage plan is subsequently made, showing the work as actually put in. The contractors are benefited by it, because they know better on what work and what quantities to base their estimate. Their workmen on the

building are likewise benefited, because they can find by referring to the plans where the pipes are intended to be run. The architects and the building superintendents are benefited because they do not have to answer so many questions to the foreman in charge of the plumbing and drainage, and because their time is not so much taken up at the buildings in course of construction with the laying out of the sometimes complicated work. The many advantages, resulting from well-considered drainage plans, become particularly apparent in the case of large and important structures, such as hotels, hospitals and modern office buildings.

Another improvement relates to plumbing and drainage specifications. While formerly plumbing specifications were somewhat indefinite and too general in character, with the inevitable result that estimates for the work ran widely apart, it is now universally recognised that plumbing is a question of vital importance in building construction, and much more care is exhibited in the preparation of the specification. Other things being equal, it is self-evident that the more thoroughly detailed and accurate the specifications are—which does not necessarily mean elaborate—the closer will the bids for the work run, and the more will the finished work conform to the expectations of the architect or his client. In this connection, permit me to state that the too general use of the printed blank plumbing specifications of the Building Department for contract work is not, in my judgment, to be approved. Such blank forms may be exceedingly convenient and labour-saving for the inspectors of the Department, but for all, except the smallest houses or tenement buildings or simple warehouses, they are not sufficiently detailed. A contract for a large job should be based on a separate type-written or printed specification. Too much care cannot be bestowed upon the specification. It is my experience, and doubtless it is yours, that the number of extras in the final plumbing bills is inversely in proportion to the completeness of the specification. I refer here, of course, only to the extras which the architect finds himself compelled to order, owing to omissions in the original specifications, and I do not include those sometimes quite numerous extras which owners or building committees require.

Now let me turn to the question of materials. Here, too, we cannot fail to find numerous and important improvements. Formerly the house-drain inside the building consisted of earthenware pipes. The soil-pipes were run of lead pipe, with

SHORLAND'S PATENT COMBINATION OPEN FIRE-PLACE MANCHESTER STOVE

hand-made seams. You are, I trust, sufficiently aware of the objections to such materials. Happily they have gone out of use. The first improvement consisted in using iron pipes for drains and soil-pipes. For many years it was customary to use the so-called light or standard plumber's soil-pipe. When the testing of drains by the water-test began, the objections to these pipes at once became apparent, it being a most difficult matter to caulk joints in light pipes so as to be permanently air and water-tight. Hence it came about that at least in the case of the better class of buildings, extra heavy cast-iron pipes were specified. From this time dates the curious practice, which I have often met, of specifying heavy pipe for the main drain and light pipe for the vertical soil and waste-pipe lines. Still later, when the practice of "back-airing" traps began, we find heavy pipes specified for both the drain and the soil-pipe system, whereas light pipes were considered sufficiently good for vertical lines of vent-pipes. A chain is not stronger than its weakest link, and I know you will agree with me that it was a mistake to use two grades of pipe for the soil, drain and vent-pipe system of a building. As is well known, the use of extra heavy pipes is now in this city compulsory in all classes of buildings, from the cheapest tenement-house to the finest private mansion. It is perhaps well that the rule is compulsory, for otherwise we should find unscrupulous plumbing contractors and speculative builders still making use of what they must know is an unsatisfactory material for drainage. Castiron pipe, even of the heaviest and best quality, is apt to have sandholes or imperfect seams, hence by far the greatest security lies in ordering from the manufacturers pipes and fittings which have been tested at the foundry by hydrostatic pressure.

The most recent improvement, as regards this point, consists in the more extensive application of screw-jointed wrought-iron pipe for drainage purposes, particularly in the case of high buildings. Having been to some extent personally connected with the introduction of this system in the Eastern States, I cannot help remarking that a wonderful change in opinion has taken place in architects' offices, and to a certain extent also in plumbers' shops, regarding the merits of wrought-iron pipe and the use of screw-joints in place of lead-caulked joints for purposes of drainage. It is scarcely ten years ago when it was my privilege as engineer of a now defunct house-drainage company to discuss with architects the advantages incident to the new method of drainage. A few architects went on record as in favour of the screw-joint construction. The majority, how-

ever, guided in many cases by the advice of the plumbers estimating in their offices, were opposed to the use of wrought-iron for drain, soil and vent-pipes. The pipes which were used then by the advocates of the screw-jointed wrought-iron system were without exception protected against rust, either by a thorough application of coal-tar, or by dipping the pipes while heated into a bath of hot asphalt, or else the pipes and fittings were made rustless by the Bower-Barff process, or finally galvanised pipes were used, particularly for vent lines. You will readily understand my surprise to find at the present time buildings in which plain wrought-iron pipes are used for purposes of house-drainage, the pipes not being in any way protected against corrosion. The mistake—for mistake it is—can be explained only by the fact that the Building Department requires cast-iron pipe to be plain and uncoated, but wrought-iron piping should in my judgment always have some protecting coating against rust.

Other improvements relating to materials consist in the more extensive use of drawn-lead traps and of brass traps, in place of cast-lead pipes or of lead traps with hand-made seams. I must, however, sound a note of warning against the use of certain brass traps with cast partitions, which are often found to have sandholes, and are then of course only a delusion and afford no protection against sewer-air. The use of very light brass tubing for exposed or vent pipes should be guarded against, as also the use of light brass traps or of traps with rough inside surfaces. Finally, the brass pipe should be of iron-pipe size, i.e. full bore and not restricted in diameter.

I pass on now to the consideration of important recent improvements regarding the sizes of pipes used for drainage purposes and the manner of laying the drains. Of the old brick drains of large size, square in shape and ill-adapted to the removal of household wastes, it is not necessary for me to speak, as they belong to a former generation, although they are occasionally, even now, unearthed in the overhauling of older mansions. Up to within a recent period it was the custom to use for house-drains round pipes which were much too large in diameter to perform their function in a proper manner. Even the smallest house had a 6-inch drain; larger buildings had 9, 10 and even 12-inch pipes. There is no advantage, and there are considerable disadvantages, in using pipes of too large bore. The old-fashioned absurd ideas regarding the necessity for large pipes are now abandoned. The use of small drains is a distinctive achievement of modern sanitary drainage. It is usual, at present, to use a 4-inch pipe

"OPTIMUS" MAGIC LANTERNS SUITED FOR DRAWING ROOM AND LECTURE HALL.
Each Magic Lantern is efficient for exhibitions. The Lens gives crisp definition, being a superior Achromatic Photographic Combination with rack and pinion. It is fitted to a telescopic lengthening tube, so gaining increased focal accommodation. The Condenser is composed of two plano-convex lens of 4 inches diameter. The refrugent lamp has 3 wicks, yielding a brilliantly illuminated picture. Each is complete in box. Pairs for dissolving arranged in one Box at same prices. Lever Dissolver, 8s. 9d.

for the smaller houses. An average sized four-storey dwelling can be sufficiently sewered by a 5-inch drain, and a 6-inch sewer is sufficiently large for a mansion. Extensive buildings, such as institutions, office buildings, &c., may require a pipe of larger discharging capacity; but in that event it is preferred to use two or more drains of restricted size as being more liable to be self-cleansing.

To illustrate. The entire waste water from the plumbing fixtures in such an extensive building (vertically) as the Manhattan Life Insurance Company's building, comprising 205 washbasins, 24 sinks, 52 urinals, 62 waterclosets, and including all the roof-water, besides various other wastes, is successfully removed by means of two 6-inch pipe-sewers laid with a fall of $\frac{1}{4}$ -inch to the foot.

The same principle applies to the soil and waste-pipes of houses. Formerly 5 and 6-inch soil-pipes were commonly used in private houses, and the sink waste-pipe was at least 3, and often 4 inches in diameter. It is now the rule to make soil-pipes of private dwellings 4 inches, and kitchen-sink wastes are purposely restricted in size to 2 inches, in order to be more self-cleansing. As regards the branch wastes from fixtures, the modern tendency is to use small pipes, and not only a vast improvement but also economy in design is thereby effected. The traps under fixtures are likewise restricted, with the advantage that they are kept better flushed. It is under any circumstances a difficult matter to keep traps perfectly clean, but better results are undoubtedly attained where the diameter of traps is restricted, in order to concentrate the stream, and thus utilise the same in scouring the channel.

One other point in connection with sizes of waste-pipes is worth mentioning: I refer to the rain-water or conductor pipes. The sizes of these pipes—in fact, of all vertical pipes—cannot be determined by mathematical rules. Whereas sizes of horizontal or graded pipes can be calculated accurately by means of hydraulic formulas, or by tables evolved from these, I know of no rule by which to determine the diameters of leader-pipes for roofs of given areas and of known pitch. I have likewise been unable to find rules derived from practical experience or from actual tests and experiments, although I have hunted high and low for them. The only rule which I was able to find was in a recent German architectural text-book, according to which publication the diameter of a leader-pipe may be determined by allowing an area of 1 square inch in the pipe for each 60 to 70 square feet of roof-surface. I presume the smaller size is intended for roofs of a flat pitch,

and the larger size for steep roofs. It is not stated for what rate of rainfall the rule is applicable. Speaking generally, heavy rainfalls are much more frequent in our climate than in Germany, so that I should advise increasing, where this rule is followed, the diameter obtained, somewhat, to provide for efficient roof-drainage in case of very heavy sudden showers. This question of determining the size of conductor pipes is one that constantly occurs to architects and sanitary engineers, and it is to be hoped that experiments may be undertaken tending to the solution of the problem from a practical point of view.

This brings me to another question, viz. the manner of laying drains. Whereas formerly drains were buried in the ground, and thus became entirely inaccessible, it is now much preferred to carry the main drain of a house in plain sight above the cellar-floor, either suspended from the ceiling, or fastened along the cellar wall. Until quite recently it was the rule, where the drain was unavoidably laid beneath the cellar floor, in order to drain fixtures on this level, to place the drain in a trench formed of brick walls with a concrete bottom, and covered with an iron cover. The drain was thus kept accessible in its entire length. A few architects and some engineers still favour this method of construction. In my judgment, it is more preferable, after the underground drains have been thoroughly tested and made watertight, to bed the same in concrete, and to rely for access upon a number of suitably placed and suitably arranged cleaning handholes, made accessible by brick manholes with iron covers. Underground trenches, as usually built, are too liable to become rat runs, to accumulate dampness and dirt, and to constitute harbouring places for vermin. Such inspection and cleaning handholes are very desirable in a drainage system, and they should be abundantly provided even where the pipe is carried above the floor, in order to avoid the cutting of pipes, a habit only too common with thoughtless mechanics in case of a stoppage in the pipes.

Let us now give brief consideration to a further point, in which house-drainage has been greatly improved. Some years ago plans for the drainage of houses were submitted to me, in which the water-closet pipes or soil-pipes were kept separate and distinct from bath, lavatory and sink wastes. This double system, as you will readily comprehend, rendered the drainage system much more complicated and vastly more expensive without any corresponding advantage. This mistake, doubtless, arose from following too closely the prevailing

English practice as described in the English text-books on plumbing. In the absence of any practical American books on house drainage and plumbing, architects had to rely largely, ten and more years ago, on the study of English works on drainage. It is not necessary nor even desirable to do this nowadays, as there are available several good books on the subjects by American authors, which clearly describe the American practice. Other features of the English practice of draining houses which are equally inapplicable here on account of differences in the climatic conditions, are the placing of the soil-pipes on the outside of the house and the running of the smaller wastes, such as bath and basin wastes over outside gullies.

A further curious mistake which I have encountered in plumbing plans is the requirement that in case of bath-rooms with water-closets located vertically over each other on succeeding floors, there should be a separate line of soil-pipe for the bath-room of each floor, thus entailing a needless complication, a multiplication of soil-pipe stacks and a greatly increased cost of the plumbing. The exactly opposite principles are followed to-day: the work is simplified as much as possible; plumbing fixtures in houses, planned by architects, are grouped together, and the drainage is concentrated as far as practicable in a single line of pipe, thus securing an abundantly flushed line, and economy in construction.

Not very long ago the pipes pertaining to the drainage system of a house were universally put out of sight, and the fixtures concealed by expensive but useless cabinet-work. Drains were placed under the cellar floor and rendered inaccessible, soil-pipes were built into the walls, waste and vent pipes bedded in plastered partitions, supply pipes were run under hard wood or tiled floors. In case of accident to any of the pipes nobody knew where to look for them, floors were torn open, the plastering cut, rich wall decorations destroyed in the efforts to reach the pipes. One of the chief features of modern work is the exposure of all pipes. Architects and owners have now become accustomed to this improvement; there are many who even fancy the new arrangement. By a clever study of the house plans it is often feasible to carry pipes exposed, *i.e.*, outside of walls or partitions, even on the parlour floor. I have found on this floor the main pipe lines kept accessible by a hard wood hinged pipe casing, in some houses built by our most prominent architects. What a great contrast with the builders' method of the past of boxing everything up, pipes, fixtures and all.

(To be concluded.)

THE WATT ANNIVERSARY.

THE Watt anniversary lecture, under the auspices of the Greenock Philosophical Society, was delivered on the 18th inst. by Dr. Francis Elgar in the Watt Museum Hall.

Dr. Elgar said he esteemed very highly the honour conferred on him by the invitation to lecture in Greenock on the anniversary of the birth of James Watt. Many men of the highest attainments and greatest distinction, he was aware, had occupied the position he occupied that night, and if he followed those great philosophers and illustrious engineers without the consciousness of presumption, it was only because he felt that none respected or admired more than he did the genius of the man whose memory they honoured. On an occasion like that, which was essentially commemorative and contemplative, he thought the better method would be to recall something of the vast extent and importance of the improvements due to Watt's inventions, in a field whence Greenock derived much of its fame and prosperity. He could not, of course, tell them anything new or strange, but they could with considerable profit reflect on what James Watt was, on what he did towards the creation and development of the most potent factor in modern progress, and on the manner in which his efforts had inspired others to pursue the same path of invention. Popularly a great inventor was supposed to be one who by a single brilliant stroke or series of brilliant strokes acquired fame or fortune. In some instances that might be true, but in the case of most great and valuable mechanical inventions it was not. James Watt toiled and suffered for more than twenty years after his discovery of separate condensation in 1765 before it was evident that his steam engine could ever bring anything but disappointment, financial loss and misery. "Of all things in life," he complained, "there is nothing more foolish than inventing." From 1765 to 1785—ten years before he joined Matthew Boulton and ten years afterwards—his great invention brought him nothing but sickness of heart and misery, and only in 1787 did the weary term of waiting end, and Watt, free from debt and anxiety, cease from cursing his invention and enter on peace and prosperity. Although, rather unfortunately perhaps, Watt never seriously devoted any time to the subject of steam navigation, he was in reality the originator of the marine engine, for he discovered and provided the means by which steam could be applied with advantage to the propulsion of ships. Each of his great improvements on the old engine that worked by atmospheric pressure and condensed its steam in the

cylinder was a direct adaptation to marine purposes—the separate condenser, the double action of the steam in the cylinder on both sides of the piston working the steam expansively, the centrifugal governor for automatically regulating the speed of the engine and many others. These improvements made the rudely constructed little steamers of which the *Comet* was the first possible, and the tendency had been continuously towards greater dimensions, power, speed and endurance ever since. The employment of steam power in the manufacture of machinery and in the construction and propulsion of ships had made travelling by sea swift and sure and independent of the fickle aid of the wind. It had removed the hardships of seafaring by assimilating the conditions of existence afloat to those which obtained ashore, for a passenger steamer of the better class was now a floating hotel, in which hundreds of persons lived often for weeks together as luxuriously comfortable as they could on land. The great liners now arrived at and left their terminal ports with the regularity of railway trains, and sped across the great ocean highways at rates of from 21 to 22 knots, which, taking into account that the voyages were 3,500 statute miles, compared very favourably with ordinary railway running over very long distances. One of the broadest distinctions between the ships of the past, that were built of wood and propelled by wind, and those of the present, that were built of steel and propelled by steam, was that the one was the result of manual labour and the other of the application of steam power. At the close of the first third of this century the over-sea trade of the world was carried on with ships that were all of wood, and propelled by wind. Only about 200 of the total number were over 500 tons burden, or much more than 100 feet long. They were fashioned entirely by manual power, with the aid of very simple tools, and afloat were propelled by either oars or sails that could be easily worked by the crew. The builders had no machine tools or other labour-saving and labour-helping appliances to aid them in the preparation of material and in the building of the ship. Modern ships, which the Clyde turned out in large numbers, were very differently fashioned; practically everything was done by steam power variously applied. By steam power the plates which formed the hull were rolled and cut, drilled, bent to form, and in many cases rivetted; by steam power also were the vessels on completion propelled, steered, pumped and drained, ventilated, lighted, loaded and discharged. The anchor was weighed, guns were trained, loaded and fired, and all the principal working opera-

tions were carried on by the aid of steam power. Between the ship of 2,000 years ago and the trading vessel of the last century there was very little difference in the matter of size. It was the application of steam power to propulsion and to manufacture that brought about about the production of vessels whose proportions were previously unapproachable. Steam power had not only provided a means of propulsion that was certain and regular in its action, it had in facilitating the manufacture of the raw material out of which ships were built enabled the dimensions to be very largely increased, with great increase of accommodation, comfort and safety. In smaller vessels the same degree of safety could not be obtained. Safety was a quality that was greatly increased by growth in dimensions. Taking everything into consideration, he thought they would agree that the inventions of James Watt were really the source of the improvements which had made ocean navigation what it was. Watt's steam engine was undoubtedly the greatest invention of modern times, and the one which had had the farthest reaching influence on the progress of the world. In Watt the philosopher and the mechanic were combined. If he had been merely a mechanic he could not have made the discoveries in natural science that were at the root of some of his principal inventions; if he had, on the other hand, been only a mathematician or a philosopher, he could not have embodied the results of his theoretical investigations in a practical working steam engine. He was the typical engineer, possessed of mechanical skill and experience, scientific knowledge and capacity, great powers of observation and original investigation, energetic, patient and persevering. Certain of these qualities other great engineers had possessed, but in none but Watt were they all together in such measure or so harmoniously blended. The benefits this country had derived from the application of the development of Watt's steam engine to ocean navigation could not be over-estimated. The development of our foreign trade had enormously increased the wealth of the rich and ameliorated the lot and brightened the lives of the poor, built up our manufacturing greatness, and enabled food to be brought from abroad in large and regular supplies at less than it could have been produced in this country. But although we had been favoured above most other peoples by all these changes, we should not forget that the privileges we enjoyed did not include immunity from danger. The relative perfection of ocean navigation increased our responsibilities and made more difficult the task of preserving unimpaired our heritage of power. The conditions

which made ocean navigation easy, swift and sure for us made it easier also for possible enemies to attack us. The great problem for this country, therefore, was how best to protect itself and the ocean routes over which its food and raw material came against possible dangers of the kind he had indicated, and at the same time enjoy all the advantages and rewards of the prosperity which was its cause. It was on the sea that the real danger would arise, and on the sea it would have to be met. Therefore it was to be hoped that the nation which had covered all the seas of the world with its ships would show no want of energy and enterprise when the question was the defence of what it had produced with so much success and out of which it had reaped so rich a reward. If we shirked our responsibilities, the commercial greatness we owed to the genius of Watt would after all prove to be a curse instead of a blessing, and Britons be unworthy countrymen of the great engineer who had learned the world how, to quote Mr. Boulton's reply to Boswell, to "manufacture power."

NATIONAL ASSOCIATION OF MASTER BUILDERS.

THE thirty-fourth half-yearly meeting of the National Association of Master Builders of Great Britain was held on Tuesday in Birmingham, the mayor, Alderman Fallows, having granted the use of the Council Chamber for the purpose. Representatives to the number of eighty-six attended from Birmingham, London, Liverpool, Bath, Bristol, Derby, Hull, Manchester, Salford, Huddersfield, Cardiff, Bolton, Crewe, the Potteries and other parts of Staffordshire, Cambridge, Preston and Kidderminster. The Mayor gave the delegates a hearty welcome to Birmingham, and expressed pleasure at seeing so large a gathering, representing one of the chief industries of the country—an industry to which all classes of the community were so deeply indebted, and which at the present day was being carried on in many respects in a manner of which it might be proud. The president of the Association, Mr. John Bowen, then took the chair, and gave a short address. The report for the past half-year was presented and adopted, and the hon. treasurer, Mr. C. W. Green, presented the balance-sheet, which showed the Association to be in a sound financial position. The officers were re-elected:—Mr. J. Bowen, president; Mr. T. F. Ryder (London) and Mr.

J. S. Jones (Liverpool), vice-presidents; Mr. C. W. Green (Liverpool), hon. treasurer; and Mr. W. H. Smith (Northampton), hon. auditor. Matters of interest to the building trade were discussed, and the meeting concluded with a vote of thanks to the Mayor for the use of the Council Chamber, and to the President for his services to the Association. It was decided to hold the next meeting at Leicester in July. In the evening the delegates, with the local members and a number of visitors, were entertained by the president (Mr. Bowen) and the president of the Birmingham Association (Mr. T. Barnsley) to dinner at the Great Western Hotel, the company numbering about 140. Mr. Barnsley presided, and among those present were the Mayor, Mr. J. Bowen, Lieutenant-Colonel Stanley G. Bird, Major J. Barnsley, Alderman Edwards, Councillor Parkes, Councillor Baker, Messrs. J. C. Holder, W. Henman (president Birmingham Architectural Association), W. Sapcote, Aston Webb, C. W. Green, Allen Edwards, J. C. White (Liverpool), C. H. Barnsley (Preston), J. Randall (London), J. H. Marsden (Bolton), Banks, Mawson (Leeds), R. Beevers (Hull), F. W. Lloyd (building surveyor to the Birmingham Corporation), J. Botteley, T. Hill, A. G. Buller, J. C. Nicoll, J. Walker, J. S. Hassall (of Liverpool, secretary of the Association), and E. J. Bigwood (secretary of the Birmingham Association), &c. Apologies for absence were received from Alderman Johnson, Messrs. R. Neill, jun. (Manchester), J. M. Burt (London), J. Stevenson Jones (Liverpool), W. Southern (Salford), F. May (London), W. H. Bidlake, W. S. Till (city surveyor), &c. The toasts of "The Queen" and "The Prince and Princess of Wales" having been given, Mr. C. H. Barnsley proposed "The Army, Navy and Volunteers." Lieut.-Colonel Stanley, in his reply, pointed to the war in the East as illustrating the importance of having the forces of the country well equipped, and of having an efficient navy. Major J. Barnsley, whose name also had been coupled with the toast, expressed the opinion that the volunteers in Birmingham did not receive the support from the city to which they were entitled. The president of the National Association (County Alderman John Bowen) proposed "Our City," and referred to the Town Hall and the public buildings that had been erected and begun by the Corporation and other public bodies, down to the Technical School, as works of which the city as well as the designers and builders might well be proud. The toast was coupled with the names of the Mayor and Alderman Edwards. The Mayor, in responding, said that if there was one thing he was proud of

it was that he was a Birmingham man, not only by birth, but by descent. His grandfather was a Birmingham solicitor, and his father was a Birmingham builder and worked with their President at the bench. Birmingham had been called the best-governed city in the world, but they did not claim the title themselves, for the title was given to Birmingham by an American after visiting many other cities. If the title were not deserved the Council would not rest until they had earned it. The buildings of Birmingham were well worthy of the inspection of the members of the National Association of Master Builders. In addition to those that had been mentioned, he would call attention to the Grammar School, which formed the stepping-stone to fame of Charles Barry, the architect of the Houses of Parliament. He might also mention the public offices in Moor Street, which at the time of their erection were considered an important building, and of which his father was the architect and builder. With regard to the Victoria Courts—the designer, Mr. Aston Webb, and the builder, Mr. Bowen, whom they were proud to have among them that evening—he was happy to say that he was the means, by proposing a resolution in the Council, of throwing the designs of that building open to competition, and he thought he was justified by the result. Alderman Edwards traced the growth of the city architecturally and in other respects. This he attributed partly to its central position and healthy elevation, and in no small measure to the public spirit evoked some twenty-five years ago by their great townsman, Mr. Joseph Chamberlain, who devoted his enormous abilities to the uplifting of the city life, and with the assistance of devoted colleagues had raised it to the high position it now held. Mr. Sapcote, in proposing “The Institute of British Architects and the Birmingham Architectural Association,” mentioned that in 1862, according to the directory, Birmingham had forty-six architects and 152 builders, while in 1894 the city had 111 architects and 343 builders. Mr. Henman, architect, spoke of the suggestion that every local governing body should have a department of works, and carry out its own building operations, as one of the follies of youth. The Corporation of Birmingham had wisely abandoned some of its infantile practices, and was to be commended upon the way in which for many years past its public buildings had been erected. He said this not with any disrespect to the permanent officials of the Corporation, but from the feeling that the procedure he condemned was inadvisable on several grounds, not the least of which was that

of economy. Mr. Aston Webb complimented the city upon having had the Victoria Courts built by Mr. Bowen as well as they possibly could be built, and upon the prospect of possessing a magnificent House of Mercy in the new General Hospital. Neither architects nor builders were to be held responsible for long rows of jerry-built houses; the men who were responsible were, in the majority of cases, persons who had not a workshop or even a yard. The toast of “The National Association of Master Builders of Great Britain,” coupled with the name of County Alderman Bowen, was given by the Chairman; while that of “The Birmingham Master Builders’ Association” was given by Mr. C. W. Green, the Chairman responding. The concluding toast, “Our Guests,” was proposed by Major Barnsley and responded to by Mr. J. C. Holder and Councillor Parkes.

PATENTS.

[This List of Patents is compiled specially for this Journal by Mr. G. H. Rayner, of the firm of Rayner & Co., Consulting Patent Agents, 37 Chancery Lane, London, W.C., from whom all particulars and information relating to Patents may be had gratuitously.]

APPLICATIONS FOR PATENTS.

- 393. William Eckstein and John Alfred Whitmore, for “Improvements in ventilators.”

- 479. John Tourtel, for “Improvements in locks.”
- 529. Charles Henry Rogers, for “Improvements in closet-pans and water-closet ventilation.”
- 596. William Whitehead, for “Improvements in cowl for the prevention of down-draughts in chimneys.”
- 706. Guy Locke, for “The up-draught chimney-pot.”
- 783. Alexander McBean, for “Improvements in and connected with windows.”
- 784. Edward Wilkinson, for “Improvements in draught excluders for doors and the like.”

TO INVENTORS.—Patents for Inventions, Trade-marks and Designs secured; every assistance given to inventors. Specialists in Building matters. Information free.—Messrs. RAYNER & CO., Patent Agents, 37 Chancery Lane, London, W.C.

THE WELL-KNOWN FRIEZE,

ENTITLED

“THE CORN FIELD.”

1. PLOUGHING; 2. HARROWING; 3. MOWING; 4. CARTING; 5. THE PRODUCTS OF THE CORN FIELD.

Length, Fourteen Feet Seven Inches by Fifteen Inches deep.

A Splendid Example of Colour-Work in Permanent Ink Photo,
BY M. PAUL ALBERT BAUDOIN.

This magnificent Illustration was presented to the Subscribers to “The Architect” in 1886. A few Proofs were taken, which immediately became out of print.

OPINIONS OF THE PRESS.

“We are not surprised to hear that there has been a great demand for the beautiful reproductions of the well-known frieze by M. Paul Albert Baudoin, entitled ‘The Corn Field.’ The plates have been reproduced by subscription at half a guinea the set, and so great has been their success that a second edition is being issued.”—*The Lady’s Pictorial*.
“They are beautifully done in colours by the permanent ink photo process, and form a very artistic and pleasing set at the extremely moderate price of half a guinea.”—*The Stage*.
“The well-known frieze entitled ‘The Corn Field,’ which is a splendid example of colour-work in permanent ink photo, by M. Paul Albert Baudoin, is to be reproduced by subscription of half a guinea a set. They are exceedingly artistic, and would grace the walls of any house.”—*The Gentlewoman*.

AND NUMEROUS OTHERS.

In consequence of the almost daily demand for these Plates, they have been reproduced by Subscription at Half a Guinea the Set, and are now ready for issuing.

P. A. GILBERT WOOD, 175 Strand, W.C.

May be had framed in Solid Oak Frames with Mounts, at Three Guineas the set of Five Plates.

NEW READING CASE.

To Librarians of the Public Libraries and Reading-rooms.—A new handsome Reading Case can be supplied at a nominal charge of 2s., by post 2s. 6d., on early application to the Publisher, 175 Strand, W.C.

SPECIAL NOTICE TO THE TRADE AND OTHERS.

[Extract from a lecture on Architects' Libraries by Professor T. Roger Smith, F.R.I.B.A., at University College, October 10, 1893.]

"Lastly, let me recommend the back volumes of the professional journals. In the course of years all sorts of architectural topics come up in the public press and before the professional societies, and if you hunt through the indexes of these publications when you are seeking for information which eludes you in books, you will often be rewarded."

There has been a considerable demand for the back numbers of *The Architect* during the last three or four months, which we have no doubt has arisen from the remarks made by Professor Roger Smith, as contained in the above quotation; but the consequence has been that our stock of back numbers is getting very low, and consequently, in future, the charge for back numbers of previous date to January 12, 1894, will be 6d. each.

A few of the back volumes may still be had, price 12s. each.

TENDERS, ETC.

* * As great disappointment is frequently expressed at the non-appearance of Contracts Open, Tenders, &c., it is particularly requested that information of this description be forwarded to the office, 175 Strand, London, W.C., not later than 5 P.M. on Thursdays.

EDITORIAL NOTICES.

The authors of signed articles and papers read in public must necessarily be held responsible for their contents.

No communication can be inserted unless authenticated by the name and address of the writer—not in every case for publication, but as a guarantee of good faith.

Correspondents are requested as much as possible to make their communications brief. The space we can devote to Correspondence will not usually permit our inserting lengthy communications.

WESTON-SUPER-MARE.—Feb. 1.—For Building Temporary Board School. Messrs. Price & Wooler, Architects, Waterloo Street, Weston-super-Mare.

THE *Norwich Mercury* says that during the gale and high tide on Wednesday last week the old tower at Eccles, situated upon the beach between Hasborough and Palling, collapsed and fell. Eccles parish has been one of the chief sufferers from the encroachments of the sea on the Norfolk coast, and its acreage has been reduced from 2,000 to some 290. The church was dedicated to St. Mary, and has long been invisible save when the beach has been blown clear of sand, but the old round tower has been a well-known sea mark for many years.

BENNETT & SONS, timber merchants and moulding manufacturers, Manchester, have just issued the first of a new series of catalogues of standard wood mouldings for use of cabinet work and cabinet makers, with price list included. In bringing before the public this catalogue of straight mouldings, Messrs. Bennett & Sons state that they have applied several new improvements to their moulding machines which will enable them to manufacture mouldings of the best workmanship, cleanly cut and sharp (equal to the finish of their Goehring mouldings), in any kind of wood, and also that they will be pleased to execute orders for special designs in any kind of wood.

WINSOR & NEWTON'S

"Waterproof"

INDIAN INK.

SIZE OF BOTTLE, PRICE 1/

This new preparation—made from genuine Indian Ink—has been introduced to meet the requirements of those Artists, Architects and Designers who wish to lay washes of colour over drawings in ink.

Unlike many so-called Indelible Inks, "Waterproof Indian Ink," when dry, will be found absolutely unaffected by subsequent wetting.

London, Newcastle, Manchester, Glasgow, Sydney,
Johannesburg, Bilbao, and Rotterdam.

TRADE NOTES.

THE peal of eight bells are being rehung in St. Giles's parish church, Northampton, in a new iron frame by Messrs. Taylor & Co., of Loughborough, and the clock is being restored and having Cambridge chimes fitted by Messrs. John Smith & Sons, Derby. The whole of the work is being carried out under the supervision of Mr. Holding, architect, of Northampton.

THE new convent schools, Strabane, are being warmed and ventilated throughout by means of Shorland's patent Manchester grates and improved inlet panels, the same being supplied by Messrs. E. H. Shorland & Brother, of Manchester.

WE are informed that the Hornsey District Council have placed the contract for supplying 100 cast-iron street gullies, the estimates for which appeared in a recent issue, in the hands of Messrs. J. C. & J. S. Ellis, of Sheffield, Messrs. Moreton, of Westminster, having withdrawn their tender.

ELECTRICAL.

THE Board of Trade have addressed a letter to the London County Council stating that, after a careful consideration of representations made at the recent hearing of all parties, they are not prepared to hold that sufficient reasons have been advanced either on the ground of public safety or of want of parliamentary sanction, to justify them in refusing to approve of a system of electric supply which involves the use of transforming chambers under the public streets; but that they at the same time consider that the use of the public streets for such a purpose should be as much as possible limited, and that the chambers should be placed where they do not unreasonably interfere with underground works of any kind.

THE tramways committee of the Leeds Corporation recommend the adoption of an electric system of haulage for the city tramways.

THE electric light has just been inaugurated in Belfast, being made use of by several large establishments—the Theatre Royal, the Alhambra Music Hall, the Ulster Bank, and most of the large trading houses in the centre of the city. It is under

Corporation auspices, the central station being situate in Chapel Lane. The streets will not be lighted by it at present, but the light will be at the service of any members of the public who choose to purchase it. The work of installation was planned by Professor Kennedy, of London, and carried out under his superintendence by Mr. McCowan.

At the meeting of the Royal Scottish Society of Arts a paper on "Filter Press Machinery for Sewage Disposal Works" was read by William Fairley, C.E., dealing with the most recent practice of disposal in destructors by steamships, as carried out by the London County Council, and filter presses. In the course of the discussion on the paper the question of electrical treatment was raised, and Mr. Fairley stated that shortly there would be brought before the public a system by which the process of electrical treatment would be very much cheapened. At present where electric light stations had been put down it was well known that the great cost was owing to the unequal load during the twenty-four hours, and he had a proposal by which the whole of the sewage would be treated by electricity. The filtering medium would be used to assist and generate steam, and the whole process of sewage purification and lighting of the public streets would be overtaken by the same engine, plant and the same manual labour, thus reducing the cost of lighting and of purification.

BUILDING AND BUILDERS.

THE committee of the Harrogate Cottage Hospital have made a recommendation to the governors and subscribers to increase the accommodation of the institution by providing seventeen additional beds.

PLANS for the enlargement of Crief Post-office have been prepared. The increasing business during the last ten years has rendered the present accommodation inadequate.

IT is proposed to reconstruct the Arbroath Railway Station and to carry out extensive improvements.

AT the meeting of the Edinburgh Dean of Guild Court a warrant was granted to the Rev. W. Kilpatrick and others,

TOTTENHAM COURT ROAD
LONDON. W.

CARVED OAK AND ANTIQUE DEPARTMENT, No. 204 TOTTENHAM COURT ROAD.

Gorgie Free Church trustees, to erect a new church and offices at Slateford Road. The church will in the style of its architecture be based on Scottish fifteenth-century work. The plans, prepared by Messrs. M'Arthy & Watson, Frederick Street, Edinburgh, show a substantial building, measuring in extreme length in the interior 89 feet, and in width 51 feet, providing sitting accommodation for 760 persons. The estimated cost of the church is 4,300*l*.

CHURCH schools have recently been opened at Needwood, the buildings having been erected at a cost of over 2,000*l*, exclusive of site, by Mr. Hamar Bass, M.P. Mr. Bass has also undertaken the erection of a new vicarage at a cost of something like 1,500*l*, the architect in each case being Mr. Robey E. Carpenter, Burton, and the contractors:—Mr. W. Sharp (Barton-under-Needwood) for the general work, Mr. Mason (Burton) for joiners' work, and Mr. Turner (Burton) for plumbing work.

VARIETIES.

At the meeting of the Carlisle Architectural Society a lecture was delivered before the members in the Town Hall by Mr. S. W. B. Jack on "Some of Our Cathedrals." No country in proportion to its size, he said, was really so rich in examples of ecclesiastical architecture as England.

THE War Department has decided to make extensive additions to the barrack accommodation at Shorncliffe Camp, and for this purpose extra land has been procured. The cavalry quarters will be enlarged, and it is contemplated to run a line from Shorncliffe Station into the camp. The coast-guard quarters at Sandgate, which were injured by the landslide, are to be pulled down and others built in their place.

A NEW dry dock, said to be the largest in the United Kingdom, has lately been opened by the Wallsend Slipway and Engineering Company at Wallsend-on-Tyne.

PLANS have been prepared for the erection of a cottage hospital at Jedburgh, the cost of which will be defrayed by Mr. and Miss M'Millan Scott, in memory of a deceased sister.

THE Middlesbrough Town Council have appointed Mr. F. Baker, of Canterbury, as borough surveyor, at a salary of 450*l*. per annum.

ESTIMATES are to be invited for the erection of the Hope Hospital, Langholme, Cumberland. The plans have been

prepared by Mr. Woods, Architect, London. The building, which is on the cottage hospital principle, will be 200 feet long by 160 feet deep.

At the meeting of the London and Provincial Builders' Foremen's Association at the Memorial Hall, E.C., Saturday, February 2, a paper will be read by Mr. Geo. Barclay on roofs and roof construction.

WE have received a sample card of pens from Messrs. John Heath & Co., of Birmingham. The No.'s 444 and 801 seem exceptionally good for a bold freehand writing. We may mention that these pens can be obtained through any stationer.

At the general meeting of the Association of Sanitary Inspectors in Scotland held in Linlithgow, papers were read on the sanitary aspects of workshops legislation and of the recent Parish Councils Act.

At the meeting of the Glasgow Association of Students of the Institution of Civil Engineers, Mr. Angus M. Stewart read a paper on "The Glasgow District Subway."

THE inhabitants of St. Margaret's Bay are becoming alarmed at the encroachment of the sea on that point and between the South Foreland lighthouses and the bay. Frequent falls of cliff are taking place at the South Foreland, and another large fall has just taken place. The effect on the foreshore at St. Margaret's is becoming disastrous. Twelve feet have been swept away since Christmas, and the erosion continues at the same rate. The mischief has been going on seriously for some years along the whole line of cliff between Dover and St. Margaret's Bay. It is supposed that the encroachment of the sea in this direction is due in some measure to the growth of Dungeness Point.

THE annual prizes at the Leamington School of Art were distributed by Dr. T. W. Thursfield, mayor. He took occasion to speak of what had happened in regard to carpet designing at Kidderminster as an illustration of the value of art education. He remembered the time when the whole work of carpet designing at Kidderminster was in the hands of Frenchmen, because no English designer could be found of sufficient art education or art aptitude for the work. Such, however, was the progress that had been made in art education that not only was the whole of the designing for Kidderminster carpets now done by English educated at Kidderminster Art School, but the students of that school were in great request throughout the country.

"MANCHESTER" DYNAMO.

SOME of the relations between geology and architecture were suggested by a lecture which Mr. Goodchild, of the Geological Survey, delivered in Edinburgh on Saturday. He argued that the direction of some of the Edinburgh streets, and even their corners, had been determined by physical conditions, and the reason of many of the architectural features of Edinburgh could not be understood unless something was known of the geological features of the district. Edinburgh consisted of a series of ridges and furrows. Princes Street, George Street and Queen Street coincided with those east and west ridges, for instance, and in Princes Street Gardens the North British Railway ran in one of the grooves. Edinburgh in that respect was typical of the district. Mr. Goodchild ascribed to glacial causes the configuration of the ground. He said there was not much doubt these great furrows and ridges had been shaped out by the action of masses of ice moving over them for centuries eastwards towards the sea. When there was an amelioration of the climate the ice vanished, but left boulders behind it, and when men came to portion out the land they left as corners and landmarks the great boulders. That applied to Edinburgh, where many of the streets had been determined by features due to glacial causes. Dealing next with the effect of volcanic action, Mr. Goodchild stated that what he termed the Edinburgh volcano must have been about the same shape as Vesuvius, and must have undergone many changes. He pointed to traces of it in the Queen's Park, the Calton Hill, Craiglockhart, and near Granton and Colinton, and expressed the opinion that the centre of volcanic action was somewhere between Arthur Seat and the Castle.

MR. VANDERBILT'S HOUSE.

It is announced from New York that Mr. Cornelius Vanderbilt, the New York millionaire, has opened his new palace with a grand ball. This building, which is to shelter about ten people during six months of the year, and to remain closed during the other six, stands at the corner of Fifty-seventh Street and Fifth Avenue, and has cost its owner 1,000,000*l.* It is of Spanish design outside, built of grey stone with red facings, turrets and battlements. It is three storeys high, with a lofty attic. The ball-room is the largest private ball-room in New York, being 75 feet long by 50 feet wide, decorated in white and gold Louis XIV. style. The ceiling cost a fortune, and is made in the form of a double cone, covered with painted nymphs and

cupids by the late M. Baudry. Round the cornice are delicately-modelled flowers, each with an electric light, while an immense crystal chandelier hangs from the centre. The walls on the night of the opening ball were covered from floor to ceiling with natural flowers, at a cost of 1,000*l.* Adjoining the mansion is the most expensive garden for its size in the world, for although it is only the size of an ordinary city lot the sum of 70,000*l.* was paid for it, and a house which had cost 25,000*l.* to build was taken down to make room for the few flower-beds.

COUNTY COUNCIL EXTRAVAGANCE.

THE following letter from Mr. T. B. Westacott appears in the *Standard*:—Much has been written and said as to the cost of painting Hammersmith Bridge, and anyone not knowing the facts would imagine that that was the only job done by the works committee of which the facts are known. With your permission, I will give a few more instances of "how the money goes."

The works committee was first appointed in December, 1892, and very soon after works were referred to them to carry out. Early in 1893 central premises at Belvedere Road, Lambeth, were taken at a rent of 1,500*l.* a year, which premises have been since purchased by the Council for 39,000*l.* Since purchasing them the Council, on the advice of the works committee, has decided to expend 13,000*l.* on new workshops, 12,000*l.* on offices, 6,200*l.* for machinery, 13,000*l.* for stables and 7,250*l.* on river wall, making a total expenditure of 90,450*l.* on the central yard. And those works are now in hand.

The number of men employed in the Works Department varies from time to time; but on the 11th instant there were 1,370 men employed, and that is less than are often employed, there sometimes being over 1,700. Although the Council resolved that the committee should, on the completion of the works referred to them, forthwith report to the Council that such works were completed, with particulars of the estimated and actual cost thereof, will it be believed that up to the present time the Council has only had particulars from them of thirty-two works which have been carried out by them? although it is well known that many more have been completed, and I do not think I am wrong in saying that between 2,000 and 3,000 different works referred to them by the Council

ART PLATES FROM "THE ARCHITECT."

Awarded Gold Medals, International Health Exhibition and Architectural and Building Trades Exhibition (1889).

PROOFS on PLATE PAPER of the following Illustrations which have appeared in "THE ARCHITECT" can now be obtained in a separate form suitable for Framing.

THE MARTYRDOM OF ST. STEPHEN. By E. J. POYNTER, R.A. Size, Forty Inches by Fifteen Inches. Price One Shilling. Free by post, carefully packed inside patent roller, One Shilling and Three Pence.

"AND THE SEA GAVE UP THE DEAD." By Sir FREDERIC LEIGHTON, President of the Royal Academy. A few Proofs of this Fine Art Plate can be obtained (if ordered at once), price Two Shillings each. Free by post, carefully packed inside patent roller, Two Shillings and Two Pence.

THE BANQUET. The well-known and beautiful Chromo-Lithograph by H. STACY MARKS, R.A. Size, Thirty-nine Inches by Fifteen Inches. Price One Shilling. Free by post, carefully packed inside patent roller, One Shilling and Three Pence.

1. AN OFFERING TO CERES. 2. THE EDUCATION OF BACCHUS. 3. MINERVA VISITING THE MUSES. 4. JUDGMENT OF MIDAS. By W. HAMILTON. Size of each plate, Forty Inches by Fifteen Inches. The whole forming a very beautiful Frieze in Bartolozzi Mezzotint. Price per set, Six Shillings on Proof Plate. Free by post, carefully packed inside patent roller, Six Shillings and Six Pence.

THE HISTORY OF JOAN OF ARC. By M. JULES EUGENE LENEVEU. From the Wall Painting in the Panthéon, Paris. Four Pictures on one Plate: 1. Domremi: Inspiration. 2. Orleans: Struggle. 3. Reims: Triumph. 4. Rouen: Martyrdom. Size, Forty Inches by Fifteen Inches, on Proof Plate. Price, Two Shillings. Free by post, carefully packed inside patent roller, Two Shillings and Six Pence.

THE WATERLOO HEROES. By J. P. KNIGHT, R.A. Dedicated, by Special Permission, to VISCOUNT WOLSELEY, K.P., G.C.B. Proofs, price One Shilling each (thin Plate Paper). Proofs (Special), price Two Shillings and Six Pence each (thick Plate Paper). Size Twenty Inches by Thirty-six Inches. Framed and Glazed in Oak, Complete, One Inch, Twelve Shillings each. Ditto, One and a Quarter Inch, Fourteen Shillings each. Ditto, One and a Half Inch, Seventeen Shillings each.

THE TOILERS OF THE DEEP. Two Tinted Ink Photographs. Size, Eighteen and a Half Inches by Thirteen and a Half Inches. Price Two Shillings. Free by post, carefully packed inside patent roller, Two Shillings and Three Pence.

JOHN SELL COTMAN'S PICTURES, lately on Exhibition at the Burlington Fine Arts Club. The Plates are uniform in size, Twenty-one Inches by Fifteen Inches. The Titles are as follows:—1. Rouen from Mount St. Catherine. 2. Breaking the Clod. 3. View in North Wales. 4. Norman Arches. 5. Byland Abbey. 6. Norwich, from the Cromer Road. 7. Dewy Eve. 8. Mousehold Heath. 9. Cader Idris. 10. Castle Eden Dean, Durham. 11. Bamborough Castle. 12. The Interior of Norwich Cathedral. 13. Mountain Pass in the Tyrol. 14. Postwick Grove.

The price of the Set is Twelve Shillings and Six Pence; by post, carefully packed in patent roller, Thirteen Shillings. Kindly order early, as only a limited number of proof copies can be obtained.

May be obtained from all Newsagents, Booksellers, Messrs. W. H. SMITH & SON'S Bookstalls, or from the
Publisher, P. A. GILBERT WOOD, 175 Strand, London, W.C.

and committees have been completed of which we have had no account or particulars.

On looking over the items in the return which has been made, we find that the industrial schools committee wanted two cottages built at Mayford, which they were advised by their architect could be built for 850*l.* The works committee said they could not do the work for less than 925*l.*, which the Council agreed to; but we find that they cost 1,116*l.* 12*s.*, on which the Council pays 3 per cent. interest. The cottages bring in 9*s.* a week, or 23*l.* 8*s.* a year, out of which the Council pays the rates.

The parks committee wanted a lodge and conveniences built at Plumstead Common, which they were advised by the Council's architect could be built for 1,070*l.* Tenders were invited, the lowest of which was 889*l.*, the next 940*l.*, the next 945*l.*, and there were four higher ones. Instead of having the work done by a contractor it was given to the works committee, whose account amounts to 1,345*l.* 0*s.* 7*d.*, being 275*l.* 0*s.* 7*d.* above the architect's estimate, and 456*l.* 0*s.* 7*d.* above the lowest tender.

A new fire station was to be built at New Cross, at an estimated cost of 16,000*l.* Seven tenders were received from respectable builders, all of them being under the estimate. The lowest was withdrawn, but instead of giving the work to the next lowest, which was 14,537*l.*, it was given to the works committee, whose account for building same was 18,789*l.* 5*s.*, being 2,789*l.* 5*s.* above the architect's estimate, and 4,252*l.* 5*s.* more than the Council could have got it done by a contractor.

A shelter for cricketers at Southwark Park was estimated to cost 474*l.* 2*s.* 9*d.*, but actually cost 632*l.* 4*s.* 3*d.*; some conveniences at Clapham Common, which were estimated to cost 707*l.* 17*s.*, actually cost 1,054*l.* 12*s.*; a boundary wall at Waterlow Park, which was estimated to cost 197*l.* 1*s.* 9*d.*, actually cost 294*l.* 18*s.* 5*d.* A retiring-place (which was in stock) was erected at Eel Brook Common, and 112*l.* was allowed by the Council for transferring, repairing and erecting it, with a proper water supply; but the accounts of the works committee show that it has cost 179*l.* 19*s.* 3*d.* A shed had to be built at Spring Gardens, which was estimated to cost 70*l.*, and when completed it was found to have cost 113*l.* 11*s.* 2*d.*; and a boundary wall at Cheyne Walk, Chelsea, cost 60*l.* 8*s.* 1*d.*, which was 17*l.* 13*s.* 11*d.* more than the architect says he could have got it done for.

The parks committee reported to the Council that in seven cases in which the works committee did work for them, at an

estimated cost of 4,142*l.*, they had cost 5,697*l.* 4*s.*, or an excess of 1,555*l.* 4*s.*, equal to 37½ per cent.

The fire brigade committee reported to the Council that in ten cases, where the architect's revised estimate was 1,148*l.*, it had cost 1,759*l.* 16*s.* 8*d.*, or 611*l.* 16*s.* 8*d.* beyond; and in five other cases, where the estimate was 175*l.*, it had cost 342*l.* 18*s.* 10*d.*, nearly double the estimate, and when questioned on the matter in the Council, the acting chairman of the committee admitted that there were over six hundred similar cases.

These are all cases that have been reported to the Council, and in which there can be no doubt as to the accuracy of the figures. May we not assume that the cases not reported on will tell the same tale, and for that reason have not been reported? There is one instance not yet reported to the Council, in which it was publicly stated in the Council that the building of the artisans' dwellings at Yabsley Street, Poplar, and West View, Greenwich, had cost 7,000*l.* beyond the architect's estimate. These cottages were at first estimated to cost 33,967*l.*, which, by the revised estimate, work out at 45,000*l.*, but which, it is stated, have actually cost over 52,000*l.*

If, as is alleged, the works committee has been such a success, is it not strange that we have not had more than thirty-two jobs reported on out of the large number that has been completed? Seeing that the committee has at the present time over 250,000*l.* worth of work in hand, is it not time that those who have to find the money should bestir themselves and take care that those only are elected members of the Council who will see that the money is carefully and judiciously expended, and that if works are to be done by men in the direct employ of the Council, they shall be done at the same cost as contractors can do the work, and not at the excessive amounts that the works are now costing? When the Council decided to do its own work it was said the contractor's profit would be saved, but the results do not bear out that promise.

As one prepared to verify every one of the statements herein contained, and who can produce the minutes of the Council to bear them out, I feel it is only right that these facts should be made known, so that the ratepayers should not be misled by the statements that have been issued by the Progressives, in which they say, "By doing our own work we are saving money." If they are, let them report on the whole of the works completed, and let the public know the whole of the results, and not rest content with the thirty-two cases they have reported on.

MR. HEPWORTH AND CARLISLE.

THE citizens of Carlisle will learn with regret, says the *Carlisle Journal*, that Mr. Joseph Hepworth, who for twenty-five years had been engineer and general manager of the Carlisle Gas and Waterworks, has resigned his appointment. The resignation was tendered on Wednesday evening to the gas and water committee, who had unfortunately no alternative but to accept it. Mr. Hepworth, it appears, is about to join as partner and managing director a large firm of manufacturers of gas-meters, whose headquarters are in Edinburgh, with branches in Manchester and the colonies. He will take up his residence in Edinburgh, where he will continue to act as consulting gas and water engineer, a branch of his profession in which he has attained great eminence. His engagement at Carlisle will terminate in April, and in the following month he will probably take his departure from the city which he has made his home for a quarter of a century. When he came to Carlisle there were two appointments vacant, and he was in some doubt which of the two he would accept. One was the management at Carlisle, and the other was a sub-managership at Cheltenham. After visiting this city he arrived at the conclusion that Carlisle offered more scope for development, and he decided to become a candidate for the appointment in this city. Another engineer was appointed to the sub-managership at Cheltenham, and the manager of the works in that town having shortly afterwards died, the sub-manager was promoted to the vacancy at a salary of 1,200*l.* a year. This incident may perhaps have suggested to Mr. Hepworth that, so far as pecuniary emoluments were concerned, he had made a mistake in casting in his lot with Carlisle rather than Cheltenham, but we question whether in other respects he has had any cause to regret his choice. During his term of office he has trebled the productive capacity of the works, and earned for himself a high repu-

tation among the members of his profession, both as a gas manager and water engineer.

Carlisle had been lighted by gas since 1818; but Mr. Hepworth found the Carlisle works much behind the times in 1870. One of his first reforms was to introduce a simple method of putting out the street lamps, a process which had previously been performed by lamplighters with ladders. This at once effected an appreciable saving of money, and it was the precursor of many improvements of much greater importance. The works then existing were found quite inadequate to meet the growing demands upon them. The quantity of gas delivered in 1870 was 80 million cubic feet, and in the next five years it had increased nearly 34 per cent. Mr. Hepworth in 1875 made exhaustive reports upon the question of extension upon various sites named, including Linton Holme, near the North-Eastern goods station, and produced very elaborate calculations as to probable requirements. The Council determined to develop the works on and near the present site, and Mr. Hepworth took entire charge and superintendence of the new buildings that were then and subsequently erected. Great improvements were soon introduced into the manufacture of gas, its purity and illuminating power were greatly improved, and no opportunity was lost of introducing into the gasworks those economical methods which have been invented in recent years, by which a much larger quantity of gas can be produced from every ton of coal carbonised. While the plant at the works was improved and developed, the mains were overhauled, leakages were prevented and the difference between the quantity of gas made and the quantity consumed was reduced to a minimum (1.64 per cent.), of which any city might be proud. The adaptation of gas to the purposes of cooking, heating and motive power was encouraged with a liberal spirit, and by the adoption of the "penny-in-the-slot" system of gas meters for small houses, the number of consumers of gas for illuminating purposes has been largely augmented. In 1870 there were under 5,000 consumers; in 1894 there were 7,171, or nearly one-half more; 642 gas cookers have been introduced; 1,297 gas fires and heating stoves; 395 gas boiling stoves and 52 gas engines. These are almost entirely new developments of the use of gas. We have not yet mentioned the introduction of the processes by which the residuals have been turned to profitable account. This also was due to Mr. Hepworth, and so rich was the mine of wealth thus tapped that at one time it seemed as if it would pay the gas committee to supply gas at cost price in order that the quantity of residuals available for

22 & 23 SOHO SQUARE, LONDON, W.

sale at high prices might be increased. The most recent work of importance carried out under his direction has been the extension of the gas mains to Scotby and Wetheral.

As with the gasworks so with the waterworks. The history of the works during Mr. Hepworth's tenure of office has been one of continuous development and prosperity. The works have been enlarged and the profits have been increased notwithstanding the reduction of the price of water to a low level. The filter-beds in Stoney Holme were doubled under his superintendence, without calling in the aid of an engineer from the outside; he designed and carried out the public baths, he took successful steps to reduce the great waste of water, and during the last two years he has been engaged in considering the best means of still further extending the works to meet the growing needs of the city. That great Mosedale gravitation scheme, by which it was proposed to bring water to Carlisle from the upper reaches of the Caldew, proved too costly and too much surrounded by unknown possibilities of compensation to find favour with the public; but we hope that before he relinquishes the appointment which he has filled with so much credit to himself and so much satisfaction to the citizens, he will be able to propound some acceptable scheme for the development of the present works. As a consulting gas and water engineer he has made himself a name in various towns in Cumberland, not to go further afield, and his election to the presidential chair of the Institute of Gas Engineers in 1890, as a preliminary to a visit to Carlisle in 1891, was most popular among the members of his profession. Mr. Hepworth has been a busy man, but he has managed nevertheless to identify himself during his residence in Carlisle with some public movements of an educational and social tendency, such as that of the Pleasant Sunday Afternoon Association and other work in connection with the Charlotte Street Church. The members of that church will join in the general regret that Carlisle is so soon to lose one who has done so much for the city, and who during the process has made himself hosts of friends.

COMBINED DRAINAGE.

A PAPER on "Combined Drainage" was read by Mr. R. Godfrey, engineer and surveyor to the King's Norton Rural District Council, before the Incorporated Association of Municipal and County Engineers on the 18th inst. He

observed that by the Metropolis Management Act, 1855, it appeared that combined drainage was authorised "with permission," and that, therefore, in the future all combined drains could be kept from becoming sewers; but in the Public Health Act, 1875, amended in 1890, there was no provision of that kind, and therefore the interpretation of the Courts, as focused by the case of *Travis v. Utley*, had a far more serious effect on provisional districts than on metropolitan vestries. As the subject was one which was exercising the minds of all municipal engineers, who were practically unanimous in the view that some alteration in the law was necessary, that Association should, in the interests of the country generally, take the lead in an endeavour to bring such pressure to bear on the Local Government Board as would bring about a speedy revision of the definitions of "drain" and "sewer," and so relieve the already overburdened ratepayer of an enormous charge which rightly belonged to the property-owner.

PORT TALBOT, SOUTH WALES.

It has been felt that a dock, with the same depth of water over its sill as at the Cardiff and Swansea Docks, was a pressing necessity for the western portion of the South Wales coalfield. In order to satisfy this want Miss Talbot, the lady of the manor, and her advisers projected a scheme for a first-class coal-port at Port Talbot, for which purpose an Act of Parliament was obtained last session. This scheme comprises a system of railways and a dock, the construction of the works for which is to be commenced forthwith. Geographically the new dock is all that can be desired. It is situated in the midst of what is practically a virgin coalfield, and by means of the railway to be made in connection therewith it will be from twelve to fifteen miles nearer than Cardiff, Barry, or Swansea to collieries having a present output of from 2,000,000 to 3,000,000 tons of coal per annum. The entrance to the dock will be protected by long breakwaters, so as to insure safety to the vessels using the port, whilst the dock itself will be fitted with the best coal-lifts and other appliances for expeditiously and economically loading ships. The engineers to the undertaking are Messrs. James A. McConnochie, P. W. Meik and T. Forster Brown, the contractors being Messrs. S. Pearson & Son, of Westminster.

IMPROVED METHODS OF HOUSE-DRAINAGE IN AMERICA.*

(Concluded from last week.)

JUST a few words on the so-called open arrangement of fixtures. A decided improvement in the character of workmanship has been brought about by the improved method of keeping plumbing fixtures exposed to view. The advantages from the point of view of maintenance of cleanliness and ease of inspection are too apparent to need further discussion. I wish to dwell, however, for a moment, upon one point which seems to be less well understood. In conversation not long ago with one of our busiest architects, he remarked that the open arrangement of plumbing fixtures entailed a largely increased labour on the part of servants and, therefore, was not looked upon with favour by householders. This is, without doubt, true of exposed nickel plated piping. It must not be overlooked, however, that nickel plated work and exposed work are not one and the same thing. You can have one without the other. From a sanitary point of view, a job may be equally well and equally safely done if constructed of lead and afterwards merely painted or bronzed. Where more elaborate or expensive work is desired, the piping may be electro-copper bronzed or finished in oxidised silver, which do not require the constant polishing which nickel finish needs to keep it bright.

Whereas in former years plumbing fixtures were scattered all over the house, necessitating a complex system of plumbing-pipes, and often endangering the health of the occupants by ill-contrived and defective fixtures placed in the bedrooms, the modern practise of architects, and one which cannot be too highly praised, is to confine plumbing-work to the bath-room, to the kitchen, pantry and laundry. The necessary fixtures are placed, at far as the house-plan permits, in vertical groups, and all appliances and the water-closet and slop-sinks in particular are placed in well-lighted and well-ventilated apartments.

There is one mistake, however, which is still frequently committed, to which I beg permission to draw your attention. The mistake to which I allude is the placing of the water closet in the same room where the bath-tub or the wash

basin are located. This is objectionable on æsthetic as well as on practical grounds. It is particularly so in the case of the smaller houses, and in apartment houses with only one bath-room. In more elaborate houses of rich people, where there are several bath-rooms, the separation of the water-closet is not so necessary for practical reasons, but I think that a bath-room with a water-closet can, in all cases, be made much more inviting by contriving an ornamental screen, or a low partition separating the water-closet from the other fixtures. The partition may be lined with marble or tiling, and its upper part may be constructed of open fretwork. I have in mind several exquisitely-finished bath-rooms designed by progressive architects, in which this division of the room was made a successful and greatly-appreciated feature.

Much improvement is noticeable in the selection of suitable and sanitary plumbing appliances.

The objectionable pan-closet is seldom encountered in modern plumbing-work, plunger-closets are out of date, valve-closets are no longer fitted up, and improved water-closet troughs have taken the place of the former privy sink. Wooden laundry tubs are no longer common, because better tubs of non-absorbent material may be obtained cheaply.

As regards the most important sanitary fixture, namely, the water-closet, the number of apparatus of different make and construction is legion. Practically, however, the choice lies between only a few approved types, viz. the flushing-rim long hoppers, which are good but require a large quantity of flushing water, and the improved pedestal short hoppers, the siphon and the siphon-jet closets, and finally the so-called wash-down closets, having a vigorous and direct flush. You may notice that I do not include in this list the wash-out closets, because while I do not wish to condemn them too severely, I cannot bring myself to regard them with much favour. They have several objectionable features, which do not commend them to me as a perfect sanitary fixture. They are, notwithstanding these facts, very popular at the present time. Popularity, however, is not always a just criterion of fitness, for the same thing may be said to have been the case with the Jennings and the Zane plunger-closets, with the Hellyer or valve-closet, &c., all of which are now out of date.

Two points require careful attention where porcelain water-closets are used, one is the floor-joint, which being on the sewer side of the water-closet trap must be made tight. The other is the connection between the piping and the earthenware horns of the bowl. If these are made rigid breakage of

the earthenware is the result of the slightest settlement of the floor. A flexible connection is, therefore, much to be preferred, and can be obtained with many of the types of closets named.

The limits of this paper do not permit my discussing in detail the requirements of water-closets, and I must pass on to review briefly the other plumbing appliances of houses.

Speaking of wash-basins, we may distinguish four principal types, viz. 1. tip-up basins; 2. chain-and-plug basins; 3. open stand-pipe overflow basins; and 4. secret waste-valve basins.

Tip-up basins are generally condemned, because in their usual form they have objectionable features. If the receiver could only be arranged so that it would not become foul, or that it was readily accessible for cleaning, this type of basin would have many merits. It is, without doubt, very convenient in use, has no concealed overflow, no chain and plug, is rapidly emptied and flushes its waste-pipe and trap well at each discharge.

The objections to the second type, the common chain and plug basin, are too well known to need further comment. It is proper, however, to state that there has recently been put upon the market some modified forms of this type, which I consider great improvements upon the ordinary type. One is a syphon basin which empties rapidly, and flushes its overflow at each discharge. The overflow channel is so shaped that when the plug is inserted in the bottom of the bowl and the same filled with water, the overflow is trapped. In office buildings and in hotels, where a stand-pipe overflow basin or a bowl with waste valve is too expensive and too complicated for general use, the syphon form of basin has much to recommend it. The other improved form is a chain and plug bowl in which the waste outlet has been greatly enlarged, and which has the usually hidden overflow channel made much shorter and accessible by means of a removable strainer.

The third type of basin has an open stand-pipe overflow, and there are numerous modifications of the device for raising the stand-pipe. From a sanitary point of view this type has, undoubtedly, the greatest merit of all forms, still my experience has been that the general public is hardly sufficiently educated in sanitary matters to appreciate its merits. By many this form of basin is utterly condemned on account of its odd shape and appearance. The favourite form of basin is just the one which has the most objections from the hygienic standpoint, namely, the bowl with secret waste-valve. To discuss its objectionable features in detail would lead us too far.

Regarding that valuable fixture for personal cleanliness, the

tub or bath-tub, with its various modified forms, such as the foot-tub, the sitz-bath, the hip-bath, the bidet, &c., I would state that tubs of wood lined with copper are less used than formerly in private houses, probably because they always require some sort of wooden casing, and also because they lose their bright appearance in use. Enamelled iron tubs, standing free from the wall and raised from the floor, constitute a satisfactory sanitary fixture, which is surpassed by the beautiful all-porcelain bath-tubs. Both kinds of tubs are now obtainable with a glazed roll rim, thus doing away entirely with all woodwork. I ought, perhaps, to mention in this connection that a great improvement in the manufacture of American earthenware has recently taken place, and that it is now for the first time possible to obtain porcelain bath-tubs made in this country. In regard to the appliances used for holding water in the bath-tub and for emptying the same, much of what I said of wash-basins applies here. In this matter I may appear to you old-fashioned, when I state that my decided preference is for an open stand-pipe overflow.

For baths in public institutions, for baths in factories, and for people's baths there is a growing tendency to discard the tub-bath in favour of the rain or spray bath, which is greatly superior from a sanitary point of view, besides having many economical advantages.

Slop-sinks and housemaids' sinks are obtainable in a variety of serviceable forms, most of them excellent from the sanitarian's point of view. I would only remark that a flushing cistern is quite as essential in the case of a slop-sink as in that of water-closets. An ingenious and novel arrangement consists in a slop-sink which flushes itself automatically each time slops are emptied into it.

Kitchen sinks are likewise obtainable in a variety of materials. This fixture is much improved by changing the dribbling stream passing through its waste into a quick and effective flush. Attempts in this direction have been made with some success, and the devices employed are certainly worth considering. Incidentally, the question of avoiding the kitchen grease nuisance is thereby solved, in a better way, to my mind, than by the employment of grease-traps at the sinks, which invariably constitute a nuisance, are usually forgotten or neglected, and are not to be recommended. I must content myself with a mere allusion to the subject.

Of urinals it is only necessary to mention that in private houses their use is not to be encouraged, as the fixture is very difficult to keep clean. In offices and in public buildings, such

as hotels, railroad stations, courthouses, &c., the fixture is a necessity, and great attention is required not only in the fitting-up but in its maintenance. The projecting lip of porcelain urinals seems to me to be of doubtful advantage. One point in the fitting-up of the fixture is worthy of mention: the bowls are generally set up too high from the floor-slab. I find it is better to set them at a height not exceeding 22 inches from top of lip to floor-line, instead of 24 to 26 inches, as is customary. The floor-slab is thereby kept more readily free from drippings.

In fitting up plumbing fixtures, the chief aim should always be the avoidance of woodwork at and around them. All fixtures should stand free from the walls, and be accessible on all sides. Even the seats of water-closets are now attached directly to the bowl; the closet thus stands absolutely free and detached from the wall, and the entire fixture can be reached for cleaning and for repairs. In one respect, however, modern plumbing fixtures are open to considerable improvement: I refer to the undesirable noisiness accompanying the flush and the discharge of the fixtures. This problem, as experience teaches, is not easily solved.

The time at my disposal permits only a brief allusion to the testing of plumbing-work. All work should be tested before acceptance, as knowledge of the safety of the plumbing-work can only be obtained in this way. I regret to say that I have found only very few mechanics doing plumbing who apply to their work any test, except where this is specially insisted upon by the architect or the engineer. To my mind, it is one of the most important duties which architects owe to their clients to see to it that all work is tested. For new work we have the water test and the air-pressure test. This should include not merely the main horizontal lines and the vertical stacks, but likewise all the branches and the brass ferrule joints. The finished work should be tested by the peppermint or by the smoke test, which help to show imperfections in the joints of nickel-plated piping and at the floor-joints. In the inspection of old work, the water test, which is the best test, cannot, for obvious reasons, be applied, and here the smoke test, or the test with oil of peppermint, intelligently applied, give valuable indications as to the condition of the work.

A great step forward would be made and plumbing-work vastly simplified by abolishing, or at least modifying, the trap-vent system.

There are at present two quite different methods of arranging the system of trapping the fixtures in a building.

In the one system, which is in accordance with the majority of plumbing regulations, and is the one at present enforced in New York City, all traps must be back-aired or vented. We thus obtain a duplicate system of pipe-lines, the work is complicated, more expensive and may become more unsafe, on account of the greater number of pipe joints and the possibility of "by-passes." The other system—the one-pipe system, as we may call it—is distinguished by its greater simplicity, economy and, as I maintain, by its greater safety. This method substitutes non-siphoning traps or anti-siphon trap attachments for the cumbersome method of back-airing. In this system all main soil and waste lines must be quite as fully ventilated by extending them the full size up to the roof as in the usual method. All fixtures are located directly at the lines carried up to the roof, or within a very few feet of the same. Siphonage of the traps is impossible under the ordinary conditions, quite as much so as in the back-airing system. You will find the majority of plumbers opposed to the new system; for while it simplifies the work, it reduces the amount of piping used and thereby the cost of the work. There is also much prejudice against the proposition, many plumbers seeming to fear that by putting themselves openly on record as in favour of it, they would by others be considered as not quite up to date in plumbing matters. The fact remains undisputed—and I have demonstrated it in many cases in my practice—that the new method is, at least, quite as safe as the old one. I venture to predict that in a very few years plumbing laws will be so modified as to leave it optional with the owner or architect of a building which method he will adopt.

This leads me to say a few words in regard to plumbing rules and regulations, in particular of those in force in New York city. Further advancement in plumbing requires the revision and improvement of the plumbing laws of the Building Department. Far be it from me to underrate the good which the present rules have accomplished in the past. Ours is not, however, an age in which we can at any time afford to stand still. Constant progress is made in every department of construction, and the researches of the practical sciences are everywhere utilised and embodied in actual practice. Let us hope to see soon a revision of our plumbing laws. Be it remembered that the plumbing rules of our metropolis are being largely copied by other cities. We cannot afford to fall behind in this matter. Our present rules are too indefinite in many details; they are much too arbitrary in others. Take, for

MAURICE'S PORCELEINE

For Painting and Preserving Wood, Stone, Metal, Plaster, or any surface on which Paint can be applied.

BRIGHTER THAN ENAMEL. EASY TO APPLY. NO BRUSH MARKS.

Cheaper than Paint and Varnish where a glazed finish is required. A Saving in Labour, only two or three coats being required on new work.

SAMPLES FREE TO ARCHITECTS AND BUILDERS.

FOR WALLS AND WOODWORK.—Maurice's Porcelaine is the best article in the market when a bright and durable finish is required; it is easy to work and gives a lasting glaze equal to China.

CEILINGS.—Our White is incomparable, and will keep its colour for years; it has binding qualities that prevent Ceilings from Cracking.

ENGINEERING.—For Iron or Metalwork of all descriptions it is a protective against Corrosion, and gives a beautiful finish, and on account of its Heat-resisting Qualities is in every way suitable for Stoves, Engines, Electrical Apparatus, &c.

SANITARY.—It is suitable for Sanitary Work, being in itself a Sanitary Invention, giving an Impermeable Ceramic Surface which will resist even HOT WATER. For Corridors, Baths, W.C.s, Lavatories, &c., it is invaluable, being Washable and Damp-proof.

APPLICATION.—It is supplied by us ready for use in drums or barrels, and is applied the same as ordinary paint, without priming of any kind.

COLOURS.—We stock 200 Tints, or can supply any other Colour or Tint within Two Hours' Notice, or the Ivory and White can be Tinted with ordinary Oil Tinters to any desired Shade.

FLATTING.—PORCELEINE is supplied to dry Flat when required.

All the above remarks are guaranteed, being the results of Practical Tests.

MAURICE'S LIQUID GOLD.—This is valuable for Interior Gilding, being an Improvement on Ordinary Gold Metallic Bronze Paints. Price, ready for use, 5/- per lb.

WRITE FOR SPECIAL QUOTATION FOR QUANTITIES TO

THE PORCELEINE CO., LANFRANC ST., LAMBETH, LONDON, S.E.

instance, the question of sizes of drain-pipes, of soil-pipes, of vent-pipes, the diameter of traps, &c. There is certainly now sufficient practical experience available to lay down more definite rules as to sizes. The rules should also in the future prohibit fixtures which sanitary science has long ago recognised as being absolutely bad. Pan-closets, wooden sinks and wooden wash-tubs should be discarded, and privy sinks should no longer be tolerated.

Before leaving the subject of interior drainage I wish to consider for just a moment the prevailing practice of doing plumbing-work. It is without doubt feasible to have plumbing-work done by day's work by a contractor of known integrity, at a certain agreed commission or profit on the net cost of labour and material without thereby unduly increasing the cost of the work. Still, as a rule, the owner prefers to make a contract for a lump sum or stated figure. In that case the recent practice, particularly in the case of high office buildings, of putting the plumbing—and for that matter the heating and power plant, the electric work, and the elevator machinery—in the builder's general contract, for a consideration which usually amounts to much more than the fee of experts who would plan and superintend the work in the owner's interest, cannot be commended. There is not, to my mind, a single feature of merit in it, and there are, on the other hand, good reasons why these branches, which comprise the domestic engineering work of buildings, should be kept separate and under the direct control of the architect or the mechanical engineer or sanitary engineering expert who may be associated with him.

In conclusion, let me say a few words about the outside drainage and final disposal of the sewage, particularly of country houses not within reach of sewers. These are questions which rarely concern the architect directly, but about which it is nevertheless useful for him to keep informed.

In the case of city houses the outside drainage is apparently a very simple matter, consisting merely in the continuation of the house-drain to the public or street sewer. Still, even the sewer connection requires attention, as is proved by a recent case which happened on the upper west side of this city, where a builder and his plumber connected a whole row of dwellings to the pipe-sewer in the street by merely breaking holes into the sewer and sticking the house-drains through it.

The final disposal of the sewage from habitations becomes a very difficult and sometimes troublesome matter in the case of country and suburban houses not within reach of sewers.

The purity of the local water-supply must be maintained, the contamination of the soil and likewise the pollution of the air must be prevented at all hazards. To accomplish this, the disgusting and health-menacing cesspool and the privy nuisance must be done away with. Bad as a single cesspool is, the evil is only aggravated by the method sometimes pursued of having one cesspool for the water-closet wastes and another for the kitchen-sink wastes, or by having a series of cesspools with connecting overflows.

Two methods of sewage disposal have been devised by engineers which offer a successful solution of the problem. One is the system of sub-surface irrigation, the other the disposal of sewage by irrigation over the surface. Inasmuch as the chief requirements are that sewage be disposed of not alone without injury to health, but also without offence to sight or smell, it is not often practicable to run the sewage over the surface of the ground near the house. Where plenty of land is available and located at such an elevation that sewage can be conducted to it by gravity, surface-irrigation is by far the best, the cheapest and the simplest mode of disposal.

The other system, the sub-surface irrigation system, has been in successful use in many country places. It has often been described and illustrated, and in a paper like this it is out of the question to go into details. The chief features of this system are the following:—

1. Carry the sewage from the house in a tight pipe conduit leading to a sewage or flush tank.
2. Collect the sewage in a double-chambered tank, the first chamber being intended to retain the solids and kitchen grease, while the second and larger tank receives the liquid sewage by a deeply-trapped overflow from the first chamber.
3. Discharge the liquid sewage once or twice a day by means of an automatic siphon into an outlet pipe leading to the sewage field.
4. Distribute the sewage by means of a main conduit with laterals into a system of absorption drain-tiles, laid with open joints in trenches 12 inches deep, covered up with earth.

I will not describe the details of the system. I wish to warn you, however, against having such work done by contract. Frequently have I been asked by clients and by architects to undertake sewage-disposal contracts, but I have always declined to do so. I know that others undertake such contracts, but the results are seldom entirely satisfactory. Often the mistake is made of laying an insufficient number of absorption tiles, with the result that after a season's work the field becomes

THE BLACKMAN VENTILATING CO., LD.,

overcharged with sewage. I also find sewage-disposal systems laid out by others giving trouble because the tiles are laid with too steep a grade, in which case it invariably happens that the bulk of the sewage runs to the lowest end of the field, where it often breaks out on the surface. In other instances, again, I find the distributing tiles laid 2, 3 and sometimes even 4 feet below the ground surface. This mistake arises from a lack of knowledge of the principles of the system, which require the sewage to be discharged into the upper well-aerated layers of the soil or the sub-surface, where the action of the bacteria converts the sewage and the particles of organic matter attaching to the earth into harmless elements.

A bad lay-out of the distributing tiles invariably results in failure. Sometimes the system proves unsuccessful from the omission of the first or intercepting chamber, in which case the tiles become choked in a short time. Insufficient attention to the flush-tank is another frequent reason why the method fails to give satisfaction. Owners of country houses, after adopting this method of disposal, generally make the mistake of assuming that the same is automatic and hence needs, after completion, no further attention. The fact is that nothing is automatic in the system except the siphon for emptying the flush-tank, but every part of the system, including the siphon, needs attention and intelligent care and occasional cleaning.

As regards the flush-tank, it may be either an open or a closed tank, the latter being preferable in all cases where the flush-tank must be placed near the house. The open tank, if at a distance from the house, is better, because it is more readily accessible and easier to clean. The tank may be circular in shape or else oblong. It is generally built of brick-work, lined with Portland cement. Colonel Waring, who introduced this system from England, has suggested lining such open sewage-tanks with enamelled-face brick or with marble. I agree with him that this is quite desirable on the ground of greater cleanliness. But in my own practice I have not been able to meet clients who were willing to incur the extra expense involved, and where I am associated with architects in such work I find they prefer putting marble or slate or enamelled-face brick where it will show to better advantage.

There are a great many other things which I would like to bring before you if time permitted. In closing this paper I thank you for your courteous attention, and trust that some of the points brought up may be new to you, though I fear that to such a progressive body of architects I have but retold an old story.

LEEDS GASWORKS.

It will be interesting to the ratepayers to know, says the *Leeds Mercury*, that the managers of the Meadow Lane, the York Street and the New Wortley Gasworks have received strict instructions from the Corporation gas committee to keep up the illuminating power of the gas to a high standard. Within the last few months there has been a considerable improvement in this respect, and, in fact, taking the whole of last year, the quality of the gas supplied from the Leeds works compares very favourably with that manufactured in other towns. The standard agreed upon between the managers and the committee is 18 candle-power. The tests last week showed an average of 18.17 candle-power. This, however, though much above the limit, can hardly be taken as a fair example, for in passing through frosted pipes the gas slightly loses quality. The coal contracts, which do not terminate until autumn next, were let at a reduction as compared with the previous year. Since the letting of those contracts the committee have received dozens of letters from colliery proprietors and others offering to supply them at still lower prices. From this it is natural to infer that business has not of late been very brisk at the collieries, and that stocks are large. At the Meadow Road Works improvements are about to be carried out (subject, of course, to the consent of the Council), which will cost upwards of 3,000*l*. The office accommodation at these large works is at present far from being convenient, whilst the workshop and stores accommodation is distinctly inadequate. All three of these defects the committee propose to remedy. The new offices will be erected on a part of the property bought for the widening of Meadow Lane, to which thoroughfare they will have a handsome frontage. At the new Wortley Works also improvements are suggested. The purifying plant there is not equal to the amount of work it should get through, and plans have been ordered to be prepared for a new apparatus. Subject to the approval of the Council, the committee also will purchase a plot of land adjoining these works from Messrs. Greaves & Holmes, to be used if necessary for extension purposes in the future. The question of appointing a successor to the late Mr. Lupton, who occupied the position of gasworks superintendent and chief clerk to the committee, has been the subject a long debate amongst the members, who have finally resolved to advertise for some one to fill the vacancy at a salary of 300*l*. per annum. To define what the duties of the new official will be is a difficult matter. In fact,

it is doubtful whether at present they could be defined. At the time the late Mr. Lupton became a servant of the Corporation, the accounts of the different Corporation departments were in the hands of different individuals. When the Municipal Buildings were erected the Council resolved that all financial matters should be controlled by the city accountant and his staff. To this rule one exception was allowed, and that had reference to the gas department. Mr. Lupton had been connected with the gasworks long before they became the property of the Corporation, and being conversant with every commercial detail of the undertaking, he was asked to retain the control of the finances. Now that the committee have lost Mr. Lupton's valuable services they have determined to readjust matters, and Mr. Derry (the city accountant) is in future to have charge of the gas accounts, and the new official, we presume, to act as superintendent of the gasworks. It is to be hoped that whoever is chosen to the new position will have a thorough technical knowledge of gas manufacture, as well as be a man of first-rate commercial capacity. A servant of the public cannot be too competent.

MANCHESTER ASSOCIATION OF ENGINEERS.

Two papers were read before this Society by Mr. G. H. Firth and Mr. D. Selby-Bigge on "Electricity as the Future Motive Power in the Textile Industries." Sir Leader Williams presided. Mr. Firth said that there was nothing of more importance in our various manufacturing concerns than the question of the transmission of power. Mechanical power was now obtained and distributed in a variety of ways, and the principal methods of transmitting it until recently were by shafting, wheel-gear, belting and ropes. But when they took into account the many objectionable features connected with these systems they would see that the day might come when these good servants must yield to a more efficient servitor. The paper next dealt with the disadvantages inseparable from the present means of transmitting power and with the unavoidable losses from friction, which was described as a "mechanical octopus." The remedy for all this waste was electricity, and the paper proceeded to consider the best means of transmitting that power. The best economical method was to have a central generating system, from which wires should be led off to other distributing centres, the current to be led off from these points to the various motors, which should be attached as closely as possible up to the point of application of

the energy in a machine. Being unable as yet to get our energy in a more direct way than by means of water, gas or steam power, the generating system was nothing more than the usual steam-engine or boiler or other motor with which we were now familiar. There was one great difference, however, not to be lost sight of, and that was that in the electrical system we usually coupled up direct on to the crank shaft of the engine, which enabled us to run at a speed usually only attained on our second or third motion shafts in the ordinary way, whereby we were enabled to use lighter engines at much less first cost for the power generated, and also at a considerable saving in space occupied. In the majority, though perhaps not all, of our textile industries, a great economy over present methods of using power might be effected, and the future alone would disclose to what extent we should have profited by the adoption of the latest development of industrial progress. The paper of Mr. Selby-Bigge was devoted to the consideration of how electricity could be generated and transmitted for the purpose of driving a cotton mill. When large water-power was available the mill might be driven with economy in a manner already successfully adopted in America—viz., by means of motors geared, or driving by belt on to the various line shafts throughout the mill. Where a good reliable water-power existed within a reasonable distance the method of line shaft driving by electric motors would be found to be an economical and advantageous one, but in the English mill district unutilised water powers of importance were few and far between, and one would almost always be brought face to face with steam power. In this part of the country gearing, belting, pulleys and shafting had been brought to a high state of perfection, and it was not by improving on these that the writer looked for saving, but to the radical change of abolishing them altogether. The upkeep of an electric power instillation throughout a mill would certainly not exceed 5 per cent. of the capital outlay, and he thought that in practice it would not exceed 3 per cent. Such machines as carding engines, &c., could all be driven electrically by motors embodied as part of the machines themselves.

At the third sessional meeting of the East of Scotland Engineering Association, held at 5 St. Andrew Square, Edinburgh, Mr. William Simpkins, B.Sc., C.E., president, in the chair, Mr. James H. Anderson read a paper on "Piled Foundations for Engineering Structures."

LONDON, W.C.

THE LONDON FIRES OF 1894.

THE annual report made by Captain J. Sexton Simonds, the chief officer of the Metropolitan Fire Brigade, states that during 1894 the number of calls for fires or supposed fires received was 4,111. Of these 845 were false alarms, 205 proved to be only chimney alarms, and 3,061 were calls for fires, of which 151 resulted in serious damage and 2,910 in slight damage. These figures refer only to calls which involved the turning out of firemen, fire-engines, fire-escapes, &c. The fires of 1894, compared with those of 1893, showed a decrease of 349; or, compared with the average of the past ten years, an increase of 521. The number of fires in which life was seriously endangered during the year was 141, and the number of those in which life was lost was 73. The number of persons whose lives were seriously endangered by fire was 204. Of these 122 were saved and 82 lost their lives. Of the 82 lost 56 were taken out alive, but died afterwards in hospitals or elsewhere, and 26 were suffocated or burned to death. In addition to these cases, 116 persons are known to have been in more or less jeopardy at fires attended by the brigade during the year. In 27 cases mineral oil lamps exploding or being upset caused 32 deaths; six children lost their lives through playing with fire or matches; four deaths were caused by candles; two by clothes coming in contact with fires in grates; two by sparks from fires; one by light thrown down; one by intoxication; one by vapour of spirit becoming ignited; one by a fire at a xylonite factory; and two by explosion of domestic boilers during the severe frost in the beginning of the year. In 26 cases, in which 30 lives were lost, the causes could not be ascertained. The number of calls for chimney-fires was 1,524. Of these 452 proved to be false alarms and 1,072 were for chimneys on fire. In these cases there was no attendance of engines, but only of firemen with hand-pumps. The total number of calls during the year, including those for actual fires, supposed fires, chimney-fires and supposed chimney-fires, was 5,635, or nearly 16 a day, all of which were attended by firemen with suitable appliances. Of the 845 false alarms received during the year, 384 were malicious calls sent through the fire-alarm call posts. In 11 cases the persons who gave the alarm were caught and punished, and ten persons were detected in the act of breaking the glass in the call points. The quantity of water used for extinguishing fires during the year was over 48,000,000 gallons, or nearly 215,000 tons. Of this quantity about half was taken from the river, canals and docks, and the remainder

from the street pipes. During the year there were six cases of late attendance of turncocks and three of short supply of water, making nine cases in which the water arrangements were not altogether satisfactory. There has been latterly a marked decrease in the number of cases in which the water arrangements at fires were unsatisfactory. Only five years ago the number of cases was 28, whilst ten years ago it was as high as 43. In addition to attending fires, the brigade kept 170,000 watches of twelve hours each, made 92,000 hydrant inspections and 108,000 fire-plug tablet inspections, maintained all the machinery and appliances of the establishment in working order, wrote many thousand reports and letters, and carried on a variety of other work.

The present strength of the brigade is as follows:—Fifty-seven land fire-engine stations, four floating or river stations, 56 hose-cart stations, seven hose and ladder truck stations, 200 fire-escape stations, nine steam fire-engines on barges, 51 land steam fire-engines, 78 6-inch manual fire-engines, 17 under 6-inch manual fire-engines, one hose tender and escape, nine hose and ladder trucks, 116 hose carts and reels, 35 miles of hose, eight steam tugs, 13 barges, 12 skiffs, 225 fire-escapes, seven long fire ladders, nine ladder vans, two trucks with ladders, two trolleys for engines, 12 hose and coal vans, six traps for visiting, one stores van, five waggons for street duties, 10 street stations, 148 watch boxes, 791 firemen, including chief officer, second officer, superintendents, and all ranks, being one man short; 20 men under instruction, 16 pilots, 75 coachmen, 137 horses, 81 telephone lines between fire stations, 57 alarm circuits round fire stations, with 565 call points, 20 telephones to police-stations, one telegraph to public and other buildings, 81 telephones to public and other buildings, seven bell-ringing fire-alarms to public and other buildings, and one speaking-tube to public and other buildings. The number of firemen employed on the several watches at the stations and with the various appliances of the brigade distributed throughout the Metropolis is at present 111 by day and 359 by night, making a total of 470 in every twenty-four hours. The average number of men available for general work at fires by night is 360. The number of accidents to members of the brigade recorded during 1894 was 115, but none of these were fatal.

As regards the causes of the fires during 1894, the report shows that 134 were due to candles, 86 to children playing with matches, 46 to children playing with fire, 99 to defective chimneys, 284 to gas explosions, gas brackets, gas escapes, &c.,

NILE IMPROVEMENTS.

ON Friday evening Sir Colin Scott Moncrieff read a paper on "The Nile" at the Royal Institution. He said that if an Egyptian were to lecture to his countrymen about the river Thames, and were to begin by informing them that he had never been above Greenwich he might be looked upon as an impostor, and perhaps he (the lecturer) was not much better, for he had never been higher up the Nile than Philæ, or the First Cataract. The whole distance by river from the Victoria Nyanza to the sea was about 3,500 miles. It might not be easy to derive any clear impression from the bare recital of mileage, and he would try to convey an idea of the length of the Nile in other ways. Standing on the bridge at Cairo, he used to reflect that he was just about half-way between the source of the Nile and the White Sea, north of Russia; or, to put it in another way, if they could suppose a river crossing the English Channel, and that the Thames should find its outlet near the Euphrates in the Persian Gulf, that river would be about as long as the Nile. Among the important services that a great river rendered to man, the Nile nobly performed the first, that of carrying off to the ocean the surplus water that fell from the skies, but with this enormous qualification, that it transported the water from tracts where there was too much, and carried it free of cost, not to waste it in the sea, but to bestow it on tracts where it was of priceless value. For most of its course the Nile fulfilled the duty of furnishing a highway through the land. Excepting a few very rude wooden wheels in the Fayun, he did not know through all the annals of the past of a single water-wheel ever turned by the power of the Nile. But that power existed to an almost unlimited extent, and might they not prophesy that some day in the future, when the long stretch of Nubian cataracts had fallen into civilised hands, and when they knew how to transmit electric energy with economy, wealth might be drawn for Egypt from its chain of barren cataracts. The unique position of the Nile was due to the benefit it conferred on Egypt in turning it from a desert into the richest of agricultural lands, supporting with ease a population of about six

hundred to the square mile. Herodotus truly said, "Egypt is the gift of the Nile." What would it mean to the English farmer if he knew exactly when it would rain and when it would be sunshine? When the Irrigation Department of Egypt was properly administered the Egyptian farmer possessed this certainty, and he had this further advantage, that it was not merely water that was poured over his lands, but during nearly half the year water charged with the finest manure. Yearly the phenomenon of the rise of the Nile presented itself, and with the most marvellous regularity. In May 1883 he took charge of the Irrigation Department in Egypt, and soon had the inestimable advantage of being joined by a band of the most indefatigable, energetic and able engineers with whom it was his happiness to work for the next nine years. He could not speak too highly of his colleagues—men who knew their work and did it, who kept constantly moving about in the provinces, badly lodged, badly fed, and denied all domestic comforts. Their first great work was the restoration of the Barrage, the dam built by Mehemet Ali at the bifurcation of the Nile, about twelve miles north of Cairo. It was a happy time to begin reforms when things were at their worst, and when every movement must be an improvement. The reformer, moreover, who had a staff on whom he could absolutely rely, and who had behind him such a strong, patient, painstaking and absolutely honest man as Lord Cromer, and who was not pestered by people who thought that they knew more than he, and insisted on giving advice, was in an exceptionally fortunate position. These works were finished in June, 1890, at a cost of about 800,000*l.*, and the annual increase of the cotton crop, even at the present very low rates, was never less than two and a half millions sterling, which had not been a bad investment for Egypt. The question of drainage had been thoroughly taken up. Twelve years ago it might be said that there were no drainage channels in Egypt; two years ago there were about one thousand miles of such channels. In 1884, when the expedition up the Nile was first being considered, he was asked by the General Officer commanding in Egypt whether he thought there was any possibility of the Mahdi diverting the river in the Soudan and depriving Egypt of its water. A Government official had no business to talk politics, and the Royal Institution was no place for politics, but he might be allowed to point out an evident enough fact, that the civilised possessor of the Upper Nile Valley held Egypt in his grasp. At this moment the Italians were on the eastern edge

of that valley, a nation who, he must say, had been consistently most friendly to us in Egypt. Supposing that they occupied Khartoum, the first thing that they would naturally and very properly do would be to spread the waters of the Lower Nile over the Soudan, and no nation in Europe understood irrigation so well as they. What would then become of Egypt's cotton crops? They could only be secured by a series of the most costly dams over the river, and the fate of Philæ would surely be sealed. But more than this—a civilised nation in the Upper Nile Valley would surely build regulating sluices across the outlet of the Victoria Nyanza, and control that great sea as Manchester controlled Thirlmere. This would probably be an easy operation. Once done, the Nile supply would be in their hands; and if poor little Egypt had the bad luck to be at war with this people on the upper waters, they might flood the country or cut off her water supply at pleasure. Was it not evident, then, that the Nile from the Victoria Nyanza to the Mediterranean should be under one rule? That time was, perhaps, far off. He concluded by giving them the assurance, to which he challenged contradiction, that at no time in the long history of Egypt—under Pharaoh or Ptolemy, Roman, Arab or Turk—had the people of the country been so prosperous or so justly ruled as during the last nine years.

PROPOSED LONDON IMPROVEMENTS.

THE improvements committee of the London County Council have prepared a report in which they state that for some time the question of the formation of an adequate northern approach to the Tower Bridge from Whitechapel High Street has engaged their serious consideration. Since the opening of the new bridge it has become apparent that the existing northern thoroughfares are altogether inadequate for the increasing traffic, and that the formation of a direct thoroughfare for the traffic to and from the northern and north-eastern districts is most necessary, and cannot be any longer postponed without serious inconvenience to the public. They have resolved to submit to the Council a scheme for a street, 60 feet wide throughout, from Tower Hill to Whitechapel High Street, by way of Mansell Street. The estimate of the officers as to the net cost of the proposed street is—for works, 74,000*l.*; for property, 276,700*l.*; giving a total of 350,700*l.*, from which has to be deducted an estimated sum to be paid by the City Commissioners of Sewers of 31,525*l.* The committee are of opinion

that the proposed northern approach to the Tower Bridge is an example of a county improvement which will add an increased value to property over a wide area, a value which will continue to increase up to a distant future. They have therefore decided to recommend that part of the cost of the proposed street should be met by a charge upon owners of property benefited, in accordance with the principles laid down in clause 36 of the London County Council (Tower Bridge Southern Approach) Bill. Plans of the area benefited will have to be deposited in Parliament, and notices will have to be given to persons affected. The number of persons of the labouring class who would be displaced by the proposed street is about 341. The committee recommend that powers be sought in the first session of Parliament in 1896 to enable the Council to construct the new street.

The committee further report upon an application of the City Commission of Sewers for a contribution towards the cost of certain proposed improvements at Upper Thames Street. The Commissioners have for many years past, as opportunities have occurred, widened Upper Thames Street, and the Metropolitan Board of Works for the most part contributed half the net cost. The Commissioners now propose to set back certain premises at an estimated cost of 37,500*l.*, and they have inquired whether, having regard to the importance of the proposed improvements, the Council would be prepared to contribute to the cost. Upper Thames Street is in some places but 21 feet wide, and by setting back the premises in question it is proposed to make the street of a uniform width of 35 feet. The committee have come to the conclusion that the improvement is a work of sufficient general advantage to London to justify the Council in contributing one-third of the cost. They therefore recommend that the Council take that course on condition that the contribution does not exceed 12,500*l.*

Both the above reports will be submitted to the Council at its meeting on February 5 next.

THE EARL'S COURT WHEEL.

ON Monday, at Brompton County Court, before his Honour Judge Stonor, the case of *Gue v. Bassett* was heard. The plaintiff, Mrs. Gue, widow of the late Walter Gue, sued Mr. W. Bassett, a contractor, of Westminster Bridge Road, for damage caused by the death of her husband while engaged on the great wheel at Earl's Court Exhibition. The damages

THE WELL-KNOWN FRIEZE,

ENTITLED

"THE CORN FIELD."

1. PLOUGHING; 2. HARROWING; 3. MOWING; 4. CARTING; 5. THE PRODUCTS OF THE CORN FIELD.

Length, Fourteen Feet Seven Inches by Fifteen Inches deep.

**A Splendid Example of Colour-Work in Permanent Ink Photo,
BY M. PAUL ALBERT BAUDOIN.**

This magnificent Illustration was presented to the Subscribers to "The Architect" in 1886. A few Proofs were taken, which immediately became out of print.

OPINIONS OF THE PRESS.

"We are not surprised to hear that there has been a great demand for the beautiful reproductions of the well-known frieze by M. Paul Albert Baudoin, entitled 'The Corn Field.' The plates have been reproduced by subscription at half a guinea the set, and so great has been their success that a second edition is being issued."—*The Lady's Pictorial*.
 "They are beautifully done in colours by the permanent ink photo process, and form a very artistic and pleasing set at the extremely moderate price of half a guinea."—*The Stage*.
 "The well-known frieze entitled 'The Corn Field,' which is a splendid example of colour-work in permanent ink photo, by M. Paul Albert Baudoin, is to be reproduced by subscription of half a guinea a set. They are exceedingly artistic, and would grace the walls of any house."—*The Gentlewoman*.

AND NUMEROUS OTHERS

In consequence of the almost daily demand for these Plates, they have been reproduced by Subscription at Half a Guinea the Set, and are now ready for issuing.

P. A. GILBERT WOOD, 175 Strand, W.C.

May be had framed in Solid Oak Frames with Mounts, at Three Guineas the set of Five Plates.

claimed were 350%, being three years' wages. The deceased was employed at Earl's Court Exhibition up till September 27 last (when he met with his death) as a workman on the axle of the wheel, 150 feet from the ground. This was supported by large columns sloping inwards, and at 5 o'clock P.M. on September 27 the order was given to stand clear for the wheel to revolve. Before the wheel could turn Gue had to be let down in his basket from the axle in order to take off a luff rope, which he did, and after doing so, it was alleged on behalf of the plaintiff that he had to get out on the nearest girder, cross over two narrow boards which were under the sloping columns in order to get to an iron ladder, and ascend again. In crossing these boards he had to bend back, and in doing so he fell and was killed. Mr. Lawless, on behalf of the plaintiff, alleged negligence, these boards being, he contended, utterly improper for the purpose; they were too narrow and were dangerous. The jury found for the plaintiff for the full amount claimed.

A NEW STONE COMPANY.

COVE, KIRKPATRICK, QUARRIES, LIMITED, is the title of a new local company which has just been formed, with a capital of 10,000l.; for the purpose of working the valuable and celebrated red and white stone quarries at Cove, near Kirkpatrick, Carlisle, the property of the Hon. Mrs. Greville Nugent. The extent of the quarry ground is nearly a mile in length, by the side of the river Kirtle. The white stone from here, lying on the east side of the river, was the material with which Eden Bridges, Carlisle, was built at a cost of 80,000l., from designs by Robert Smirke, R.A. The red stone lies on the west side, on the same range of land as the Coveshill Quarries. The west side was chiefly worked by the late Mr. Thomas Nelson, contractor, of Carlisle, for Silloth dock and railway, and many other large works which he had in hand. The present works will be connected by a siding from the Caledonian main line, worked by a small locomotive engine, and a railway laid to connect both sides of the river, so as to give plenty of quarrying ground, as the stone is very abundant, and will be easy to get. By the articles of association the company have power to work other quarries, to work brick and tile works, and to act as stone merchants, &c. London will be one of the chief markets. A large depot wharf will be kept there, and chiefly supplied by shipping, which gives a great advantage in carriage where a quantity

can be stocked. The first directors' meeting was held on the 18th inst. at the London office, 14 Great Winchester Street, E.C., when there were present the following gentlemen:—The Viscount Parker, Mayfair, London (chairman); Mr. Thomas Charteris, Westminster; Mr. James Crombie, Ramsay Road, S.W.; Mr. W. A. Bromwich, Kensington Square, W.; Mr. John Beaty, Harraby Green, Carlisle; and Mr. Alan B. Crombie, Dumfries. The bankers are the Cumberland Union Bank, Carlisle, and their London agents; the solicitors are Messrs. Angove & Bromwich, Winchester Street, London; and Mr. J. A. Bushel, 14 Great Winchester Street, E.C., is the secretary.

PATENTS.

[This List of Patents is compiled specially for this Journal by Mr. G. H. Rayner, of the firm of Rayner & Co., Consulting Patent Agents, 37 Chancery Lane, London, W.C., from whom all particulars and information relating to Patents may be had gratuitously.]

APPLICATIONS FOR PATENTS.

- 846. Robert Phillips, for "Improvements in automatic flush tanks for sanitary and like purposes."
- 869. Charles George Arthy, for "Improvements in locks."
- 908. Thomas Wilfred Woodhouse, for "An improvement in the syphon cisterns used for flushing water-closets."
- 926. George Ernest Holloway, for "Improved ventilating grate for drains and the like."
- 936. Alfred Platt, for "Ceiling protector and ventilator."
- 937. Johann Wilhelm Ludwig Rohde, for "Improvements in combination window-sash fasteners and draught excluders."
- 984. Charles James Phillips, for "Fasteners for doors, sashes, frames, &c."
- 1059. Sidney Herbert Baines, for "Improvements in sliding window-sashes."
- 1092. Charles Major, for "Improvements in and connected with fireproof and ventilating floors."

WINTER, WARMTH AND COMFORT.

HEATING AND VENTILATING APPARATUS. GRUNDY'S SPECIALTY. PURE WARM AIR.

UPWARDS OF ONE THOUSAND TESTIMONIALS RECEIVED.

PURE WARM AIR AS SUPPLIED TO

Truro Cathedral; Londonderry Cathedral; Sherborne Abbey; Kilmore Cathedral; Stanley Cathedral, Falkland Islands; Cardiff Catholic Cathedral; the Queen's School Chapel, Eton; Cork Asylum; Leicester Asylum; and to upwards of three thousand Places of Worship; and a great number of Mansions, Houses, Hotels, Hospitals, Schools, Warehouses, Factories, Workhouses; Cork Law Courts, &c., &c.

84 Brook Street, Grosvenor Square, W.: December 8, 1893.

Sir WILLIAM BROADBENT encloses cheque for the "GRUNDY" HEATING APPARATUS supplied to his house, and is glad to say that it has proved very satisfactory for warming and ventilating as required. The principle of the apparatus is most excellent. To Mr. Grundy.

PROFESSOR TYNDALL writes:—

Dear Sir,—My house being so well provided with grates and flues for the generation and distribution of pure warm air, I have been thus enabled to spend my winters in England instead of on a foreign shore.—Yours very truly,

JOHN TYNDALL.

Dear Sir,—I have much pleasure in informing you that we have found your HEATING APPARATUS a great success in our new Epidemic Hospital, which consists of a two-storey building, each storey containing two large wards, a smaller isolation ward, and two nurses' rooms. It is easily managed, does not cost much for fuel, and the air entering is most pleasant, warm, and free from smell. It is with the full concurrence of the Managing Committee I give you this testimonial. Yours faithfully, JOHN MARSHALL DAY, Registrar and Resident Medical Officer.

Fever Hospital and House of Recovery, Cork Street, Dublin: October 26, 1894.

THE

Architect and Contract Reporter.

NEW READING CASE.

To Librarians of the Public Libraries and Reading-rooms.—A new handsome Reading Case can be supplied at a nominal charge of 2s., by post 2s. 6d., on early application to the Publisher, 175 Strand, W.C.

SPECIAL NOTICE TO THE TRADE AND OTHERS.

[Extract from a lecture on Architects' Libraries by Professor T. Roger Smith, F.R.I.B.A., at University College, October 10, 1893.]

"Lastly, let me recommend the back volumes of the professional journals. In the course of years all sorts of architectural topics come up in the public press and before the professional societies, and if you hunt through the indexes of these publications when you are seeking for information which eludes you in books, you will often be rewarded."

There has been a considerable demand for the back numbers of *The Architect* during the last three or four months, which we have no doubt has arisen from the remarks made by Professor Roger Smith, as contained in the above quotation; but the consequence has been that our stock of back numbers is getting very low, and consequently, in future, the charge for back numbers of previous date to January 12, 1894, will be 6d. each.

A few of the back volumes may still be had, price 12s. each.

EDITORIAL NOTICES.

The authors of signed articles and papers read in public must necessarily be held responsible for their contents.

No communication can be inserted unless authenticated by the name and address of the writer—not in every case for publication, but as a guarantee of good faith.

Correspondents are requested as much as possible to make their communications brief. The space we can devote to Correspondence will not usually permit our inserting lengthy communications.

THOMPSON & SON, Chester-le-Street (accepted)	1,358 2 6

IMPROVED

FLAT BRICK FIRE-PROOF FLOORS.

NO THRUST ON WALLS.

The BEST as well as the CHEAPEST Fire-proof Floors yet introduced.

THEY are constructed with purpose-made hard-burnt bricks, with moulded projections protecting the iron, and provided with wedge joint throughout, forming the most compact and solid floor known.

The soffits of the bricks are specially prepared to key up the ceiling plaster. No laths or counter ceiling are necessary. They are not affected by water, acids, or alkalies, and they may be fixed during the progress of building, thus dispensing with the use of internal scaffolding.

The floors are practically noiseless, the different densities of the concrete, brick and plaster, with the air space above, intercepting the sound vibrations.

The depth of the finished floor is 6 to 9 inches only, and when the saving on this head is taken into account, the cost of a building with floors of this construction does not exceed that of one with the ordinary combustible timber floors of corresponding strength.

CONSTRUCTIONAL STEEL & IRONWORK OF EVERY DESCRIPTION.

AUSTIN'S

NEW IMPERIAL PATENT

SUPERFINE FLAX LINE.

The above article is now being manufactured and sold in large quantities for Greenhouse Sashes, Public-house Shutters, and other heavy work. The Manufacturers would recommend it for its strength, and the large amount of wear in it, consequent on its peculiar manufacture.

AUSTIN'S IMPERIAL PATENT FLAX SASH AND BLIND LINES (two Prize Medals awarded). The Manufacturers of the above articles particularly wish to draw the attention of the trade to their Imperial Patent Flax Sash Lines, of which they are now making six qualities, all of which they can strongly recommend, as they have given unqualified satisfaction to the trade for now over One Hundred Years, and the Proprietors continue to give their personal attention to the manufacture of these goods.

They also invite the particular attention of the trade to their IMPERIAL PATENT BLIND LINES, which are very superior to anything yet offered. They can be obtained of all Rope-makers, Ironmongers, Merchants, Factors and Wholesale Houses in town and country.

N.B.—Please note that all our goods, as advertised above are labelled, either inside or outside with our Trade Mark—"The Anchor."

NOTES ON NOVELTIES.

THE patent range boiler invented by T. Potterton, heating engineer, of Balham, S.W., is worthy of the notice of all architects and engineers, as it utilises the heat that is usually wasted from the kitchen fire to warm the house. It can be seen at 122 Cavendish Road, Balham, without making any appointment, warming seven rooms and conservatory, besides supplying hot water for domestic use, the range being used for cooking purposes at the same time, there being only the range fire in the house, therefore effecting an immense saving in fuel. The boiler can be fitted to any kitchen; the system, being low pressure, is therefore safe. The fire is kept burning ten hours (all night) without attention with a top feeder, which fits on the range, thus keeping the house warm and insuring hot water early in the morning. Any system is undoubtedly healthy that will keep the whole house at one even temperature and afford a great saving in labour, and diminish dirt, dust, &c. The boiler is fitted to the range, so that all parts of flue and man lids for internal cleaning are accessible without taking down coverings. If used for supplying hot water only, it gives from 100 to 200 gallons an hour, according to size, and is therefore useful for supplying baths, lavatories, laundries, hotels, &c. The patent greenhouse boiler by same inventor is also worthy of attention.

BUILDING AND BUILDERS.

SOME of the residents in Aberdeen propose to form a company with the view of building a new theatre in the city, and at a meeting just held a provisional committee was appointed to make inquiries and report the result.

AT a joint conference of the finance committee of the Middlesex County Council and the Highgate justices, held at Northfield Hall, Highgate, it was resolved to recommend to the Council to purchase a large plot of land at the corner of Archway and Church Roads, Highgate, for the erection thereon of new police-court buildings for Highgate and the district. At present the petty sessional sittings are held at Northfield hall, which has been found inconvenient and inadequate in many respects for the purpose.

THE Naval Exhibition site, on the Chelsea Embankment, has been let upon a building lease by the Commissioners of Chelsea Hospital, and is now being covered with mansions from the twenty-three designs prepared by the architect, Mr.

Delissa Joseph. The property will be known as Chelsea Embankment Court.

IN Glasgow Sheriff Court, Sheriff Balfour awarded 75% and expenses to John Macintyre, a journeyman joiner, residing at 31 Scotia Street, in an action raised by him against Matthew Henderson, wright and builder, Grant Street. The defender had a contract for the joiner-work of a warehouse in Queens Street, and the pursuer was one of the workmen required to erect and use a scaffold at certain work which he was instructed to execute. The scaffold gave way and the pursuer was thrown to the ground and injured. He maintained that the defender failed to provide suitable material for the construction of the scaffold, and that the accident was caused by such failure.

THE question of extending the present workhouse accommodation for Northampton, or of building a new workhouse, is under consideration by the Board of Guardians. The Local Government Board officials advise the building of a new workhouse, estimated to cost for site of ground and architect's commission a total of 54,000*l.*, against which an asset of 14,000*l.* or 15,000*l.* could be realised for the old buildings.

AT Atherton it is proposed to build a new Wesleyan chapel, at an estimated cost of 3,000*l.*

ELECTRICAL.

THE tender of Messrs. F. W. Ball & Co., of Bristol, has been accepted for installation of electric light in the Bristol Guildhall, and portion of the Council House.

SOME electrical engineers have recently inspected the ground from Colwyn Bay to Conway, and through Deganway to Llandudno, being the route over which it is proposed to lay an electric tramway, and at a meeting held in Llandudno expressed their willingness to accept the responsibility of laying down the whole line, including the construction of a swing-bridge over the river Conway, providing that the local authorities grant their consent.

THE watch and electric-lighting committee of the borough of Eccles have made a joint recommendation in favour of the adoption of the electric light. This, it is believed, can be effectively accomplished at the present cost of gas-lighting or at a moderate increase thereon. The watch committee are willing to enter into an agreement for the supply of electricity to the street lamps in place of the gas now supplied by the

Salford Corporation. The electric-lighting order already obtained provides that the area of supply shall be the whole of the borough of Eccles.

At the meeting of the Yorkshire House-to-House Electricity Company, Limited, held in Leeds, a dividend at the rate of 4 per cent. per annum upon the ordinary shares of the company was declared.

The tramways committee of the Leeds City Council have decided to recommend the adoption of the conduit system of electric traction in the centre of the city and the overhead-wire system for the outskirts.

At the meeting of the Worcester City Council, it was stated by Mr. Williamson that the total loss on the electric-lighting works for the first quarter was less than 100%, and he held out strong hopes that by next winter the scheme would be bringing in a profit. He further stated that the builder's extras in the erection of the generating station amounted to between 4,000/ and 5,000/. The committee regarded that as very unsatisfactory, and they proposed to inquire into the matter exhaustively, and see what extra work had been done and by whose authority.

VARIETIES.

It will be agreeable news, especially to Irish ladies, that the well-known London firm, Messrs. Oetzmann & Co., are about to open a Dublin branch on Wednesday, the 20th inst., at 61 Grafton Street, where they will supply every requisite for furnishing the home, or hotels, clubs, theatres, &c., in artistic fashion, at very moderate prices. Samples of their tapestries, cretonnes, &c., and the handsome carpets offered by Messrs. Oetzmann are to be seen at 61 Grafton Street, where, too, their Dublin manager, Mr. Walter Fleming, will supply their comprehensive catalogue. Messrs. Oetzmann will deliver free in Dublin any goods which may be ordered of them before the 14th inst.

At the Congregational church at Liscard, Cheshire, the heating apparatus set fire to the woodwork, and considerable damage was done to the pews and fittings before the fire was put out.

The fine block of buildings constituting the linoleum mills of Mr. James Williamson, M.P., at Lancaster, were almost entirely burned out. The works are the most extensive in Lancaster, and employ some thousands of people. From the beginning there was little hope of saving the building, owing

to the combustible nature of the manufacturing materials. Dense smoke from burning cork stores greatly impeded the firemen. The loss is roughly estimated at about 30,000/.

KILKENNY COURT HOUSE was partially destroyed by fire on Sunday. Luckily the outbreak was observed at an early hour, and the legal documents were rescued; but despite the efforts of the firemen, aided by the military, damage to the extent of 2,000/ was done.

At Bath, the Fernleigh Hotel, North Parade, has just been destroyed by fire. The damage is stated to be covered by insurance.

At the meeting of the Upper Stour Valley Main Sewerage Board, the question of damage to the Board's sewers by mining operations having been discussed, the engineers, Messrs. E. B. Martin and W. J. Fiddian, were instructed to communicate with Lord Dudley's mining engineers on the subject. It was also decided to accept the tender of Messrs. Cochrane & Co., Woodside, Dudley, for the supply of 2,800 tons of cast-iron pipes, at a cost of 10,442/ 2s. 3d. The Local Government Board wrote that they had recommended the Public Works Loan Commissioners to advance the Board loans of 28,353/ and 59,080/ for the purposes of sewerage and sewage disposal.

DAMAGE estimated to amount to about 20,000/ has been done by fire at the well-known Caledonia Cabinet and Chair Factory belonging to Mr. Matthew Pollock at Beith. The works, which were the most extensive in the furniture trade in the West of Scotland, were situated at the north-west part of the town. There was also a valuable stock of walnut, pollard oak, mahogany, ash, rosewood, and other valuable wood in course of seasoning, and prepared wood. Owing to frost in connections and disrepair of pipes the water could not be used for any purpose. There is a partial insurance of 15,000/.

At South Wingfield Waterworks a Local Government inquiry has been held to consider an application for sanction for a loan of 4,700/ for water supply purposes. It was proposed to take water from two brooks, two springs, and a borehole for the supply of the village, which contains about 1,300 inhabitants. There would be filter beds and a small service reservoir, and the water would be delivered by gravitation. Dr. Barwise, medical officer of health for the county, thought two of the sources of supply might be polluted by surface contamination. Mr. Strelley suggested a supply from the Oakerthorpe spring. The inspector inspected the line of pipes and site of works. Mr. W. H. Radford, C.E., of Nottingham, is engineer to the scheme.

CARVED OAK AND ANTIQUE DEPARTMENT, No. 204 TOTTENHAM COURT ROAD.

Replica of an OLD ENGLISH Carved Oak Hall Press
16th century, 5 feet wide, 7 feet 6 inches high.

A GREAT fall of cliff has taken place between Dover and St. Margaret's Bay, at Langdon Stairs, midway between the two points, and close to the coastguard station and Foreland lighthouse. An enormous piece of cliff has fallen at Foreland, representing many tons. The attention of the Board of Trade and other Government authorities has been several times lately called to the serious inroads of the sea here, and the necessity of co-operation in protecting the foreshore.

THE park committee of the West Bromwich Town Council, in a report, state that they have considered a design, prepared by the borough surveyor, for laying out the land presented by Miss Kenrick for a public park for Spon Lane Ward. The cost of the scheme is estimated at 4,738*l*. The committee recommend the Council to adopt the scheme, and to make application to the Local Government Board for permission to borrow 5,000*l*. for the purpose of carrying out the work.

AT the meeting of the Lanark County Council a memorial in reference to an improvement of the public road and the erection of a new bridge over the Kittoch Water, Carmunnock, was remitted to the committee on highways.

AN inquiry has been held by the Local Government Board at Birmingham into the application of the City Council for sanction to borrow sums amounting to 14,238*l*. for purposes connected with the public libraries and school of art, for the widening of Moor Street and for fencing and the laying-out of St. Paul's Churchyard.

THE inspector of the Board of Trade, Major Cardew, has issued his report on the recent street explosion at the corner of Cannon Street and Budge Row. He describes the immediate causes of the accidents, and adds a number of recommendations to prevent such occurrences in the future. He says if the precautions he has specified are thoroughly carried out, he considers there will be no further cause for anxiety as regards the public safety.

REPORTS upon the cathedral muniments of Worcester and Lichfield have been drawn up by Mr. Reginald L. Poole, and will be printed in a volume now in preparation by the Historical Manuscripts Commission, which will also contain the Rev. W. D. Macray's reports upon the records of the Corporations of Lincoln and Bury St. Edmunds.

AN inquiry has been held at Nelson relative to a proposed loan respecting 30,000*l*. for works of private and street improvements, 8,000*l*. for sewerage and sewage disposal, 1,641*l*. for a bridge in Leeds Road and 1,500*l*. for the completion of the Town Hall.

TRADE NOTES.

THE new additions to the county asylum, Fareham, Hants, are being warmed and ventilated by means of Shorland's patent Manchester grates, the same being supplied by Messrs. E. H. Shorland & Brother, of Manchester.

THE Cathedral at Bermuda, which was dedicated on December 21, has been lighted throughout by the "Cathedral" lamp. The *Bermuda Royal Gazette* gives a long notice of the ceremony, and mentions that "the lighting of the cathedral was tested on Wednesday evening and found in every respect excellent, a soft well-diffused light, from Jones & Willis's patent 'Cathedral' burners." The whole of the fittings were constructed under the superintendence of Messrs Hay & Henderson, architects, of Edinburgh, by Jones & Willis, of Birmingham and London.

INSTITUTION OF MECHANICAL ENGINEERS.

THE Institution of Mechanical Engineers held their forty-eighth annual general meeting in the rooms of the Institution of Civil Engineers, in Great George Street, when there was a large attendance of members. Professor Alexander B. W. Kennedy, having been re-elected president, took the chair, and moved the adoption of the Council's report for the past year. The report stated that at the end of last year the number of names in all classes on the roll of the Institution was 2,221, as compared with 2,157 at the end of the previous year. During 1894 there were added to the register 152 names, against which the loss by decease was 31 and by resignation or removal 57. The financial receipts during the past year had been 7,081*l*., while the expenditure, actual or estimated, was 5,292*l*. The capital of the Institution amounted to 38,535*l*., the greater part of which was invested in railway debenture stocks. Experiments upon the use of ropes and belts for the transmission of power, announced a year ago as about to be undertaken by the Société Industrielle du Nord, at Lille, had since been carried out, and Professor Capper, who attended them on behalf of the Institution, would make an independent report upon them in due course. In reply to a member, the President stated that a committee had been appointed to consider the question of applying a portion of the funds of the Institution to securing a place of assembly of its own in London. The report was unanimously agreed to.

THE SOCIETY OF ENGINEERS.

ON Monday Mr. Wm. George Peirce, the new president of this Society, opened the session by an address at the Westminster Palace Hotel. He noticed the papers read and the works visited by the Society during the past year, and pointed out the present satisfactory position of the Society, both numerically and financially. Next he referred to the progress of electrical traction as evidenced by the City and South London Railway and the Liverpool overhead line, the successful working of which, he said, had paved the way for the Waterloo and City electric line, of which he gave particulars. Inland navigation was then touched upon in connection with the conference in Belgium, and he observed that the great question was, whether canals should be placed in competition with railways, and so assist the agriculturist. The difficulty was that the canals for the most part belonged to the railway companies. After referring to the opening of the new lock and weir at Richmond and its satisfactory results, and the opening of the Manchester Ship Canal and the Tower Bridge, Mr. Peirce gave some particulars of the Blackwall Tunnel now in course of construction. This important public work is being constructed by a combination of methods which unite the use of the shield, cast-iron segments and compressed air. It will consist of 3,083 feet of cast-iron lining; 1,382 feet of cut-and-cover in brickwork and concrete, and 1,735 feet of open approaches, giving a total length of 6,200 feet from entrance to entrance. Up to the 2nd of January last, 722 feet 6 inches of tunnel under the river had been completed. The President then went on to deal with the question of water supply. As a waterworks engineer, he treated this subject at some length. He observed that Liverpool had now an excellent supply, and Birmingham had commenced works for supplementing her present supply by a gravitation scheme, whilst Edinburgh was contemplating a similar undertaking. Referring to the water famine at Leicester, he observed that the water storage there was too limited for the growing requirements of the town, and an

additional storage reservoir was in course of construction. As a matter of fact, water engineers generally must look to meeting future requirements, so as to avoid possible water famines in our great and growing towns. That was now being done in the Metropolis, where the daily water consumption in 1891 was 182,456,905 gallons. According to the report of the Royal Commission which had just completed its labours, the estimated daily consumption in 1931 would be 294,000,000 gallons. To meet the growing requirements, the Metropolitan Water Companies are constantly increasing their sources of supply. Those taking the bulk of their water from the Thames and Lea are opening up the gravel beds overlying the London clay. Others have been sinking wells and driving adits in the chalk, and he stated that the various operations were, as a rule, giving satisfactory results, so that, as far as the Metropolis is concerned, there would appear to be no fear of a water famine, at any rate for some time to come. After giving some particulars respecting the coal production and consumption of the world, the President concluded his address by a reference to technical education, which, he said, was of no practical value to the young engineer, unless it was combined with knowledge gained in the daily round of the factory and workshops, shoulder to shoulder with workmen.

A vote of thanks was passed to Mr. George A. Goodwin, the late president, and the premiums for papers read during the past year were awarded as follows:—The President's gold medal to Mr. T. W. Baker, "Utilisation of Town Refuse for Generating Steam;" the "Bessemer premium" to Mr. Ed. C. de Segundo, "Power Distribution by Electricity, Water and Gas;" the "Rawlinson premium" to Mr. R. Nelson Boyd, "A Deep Boring near Friestadt, Austria, by the Canadian System;" and a "Society's premium" to Mr. H. B. Ransom, "The Principles and Practice of Hydro-extraction."

CIVIL AND MECHANICAL ENGINEERS' SOCIETY.

THE Civil and Mechanical Engineers' Society visited on Saturday, February 2 (by kind permission of the chairman of the Ealing Urban District Council, Mr. Nelson; the engineers, Sir F. Bramwell, Bart., and Mr. H. G. Harris, and the Council's surveyor, Mr. C. Jones), the Ealing Electric Lighting Works, the sewage works, refuse destructors, and Jones's fume cremator. There were several points of considerable interest

to be noticed, among them being the utilisation of the waste heat from the destructors and cremator for assisting in the heating of the boilers, and the employment of the effluent water from the sewage works for the purposes of condensation. The capacity of the lighting station is 4,000 8 candle-power lamps, equal to 5,500 installed lamps; 4,125 lamps are already installed. The supply was commenced on October 3 last. The mains for lighting the streets are in duplicate, one set conveying the electric current to every alternate arc lamp and the other to the intermediate lamps, so that in the event of a breakdown through an accident the town will not be thrown into darkness. The arc lamps are in "series," the dynamos being of course "series" machines, and the "exciters" are "shunt" machines. The system adopted for domestic supply is known as the high tension, the voltage being 2,000; this is reduced by "transformers" to 100 volts before reaching the consumers' houses. The mains to the transformer sub-stations are what are known as armoured concentric. The distributing mains are single and unarmoured, and are drawn through earthenware pipes. From these distributing mains the house services are taken. The mains were constructed by Messrs. T. O. Callender. There are three Lancashire boilers 27 feet 6 inches long by 7 feet diameter, fitted with McDougall's stokers, and provision has been made for a second set of three boilers. The dynamos are of Messrs. Siemens Bros.' make, as are also the switchboards. The engines are by Messrs. Browett & Lindly, and are as follows:—Two 100 h.p., coupled direct to alternator dynamos; two 500 h.p. ditto, for the incandescent or domestic supply; two 15 h.p., for the exciter dynamos; and three engines of 40 h.p. for the arc light sets. Bellis's condensing plant will be used. Provision has been made for extension of works, which will be very soon needed, and arrangements have been made for two additional engines of 250 h.p. each. The charge made by the Council is 6d. per Board of Trade unit for lighting purposes, but for motive power, cooking and heating, only 4d. is charged. The current is measured by meter in all cases. Mr. A. P. Ford Moore represented the engineers in their absence through illness, and lucidly explained the arrangement and working of the plant.

Mr. C. Jones then took the members over the sewage works, and pointed out to them his system of getting rid of the sludge from the settling tanks, by which he did away with the expense of compressing it; and further he, by means of the sludge, enriched the clinkers from the refuse destructors

(Fryer's), and obtained a useful substance for making concrete with, a sample of which was shown, and when broken fully bore out all that had been said in its favour. The clinker when broken also made an excellent substance for metalling roads with. The system adopted for the disposal of the sewage is a simple one, being as follows:—Milk of lime is put into the raw sewage, with a small quantity of clay, and is then run into a settling tank; from here it is run off and mixed with sulphate of alumina (3 grains to the gallon), passed through another settling tank, and then run over an aerating weir and into the Thames. In the event of an epidemic of any kind the sewage after being treated would be allowed to run through a series of channels before reaching the weir, so as to expose it for a longer time to the purifying effect of light and air. The sludge is run into a tank with an impervious bottom and refuse walls, through which the water filters and is drained away, and on to the top of the sludge more refuse is thrown, and the whole is allowed to drain for about three days, and is then mixed with more of the town refuse and thrown into the destructors: the fumes of these are passed through the cremator and their noxious character destroyed. Mr. S. A. Court, C.E., on the party returning to the electric works, proposed, and Mr. E. H. G. Brewster, C.E., the hon. sec., seconded a vote of thanks to Mr. C. Jones and Mr. A. P. F. Moore, and to the engineers, for what had been a most interesting and instructive visit. The proposal was received with acclamation, and Mr. C. Jones having replied, the members returned to town.

Mr. JAMES KEITH has prepared a further report on the heating and ventilation of the Houses of Parliament, in which he points out very serious defects, in addition to those dealt with in his previous report to the First Commissioner of Works. Mr. Keith in the later report points out that the sewer-gas, which is openly liberated into the lower section of the ventilating shafts, finds its way into the committee-rooms and press gallery, and occasionally into the debating chambers of both Houses of Parliament. He further states that the atmosphere of the committee-rooms and corridors is contaminated through the arrangements for ventilating the adjoining lavatories. His chief recommendation for remedying defects are that the sewer-gas be liberated through separate pipes running to the top of the tower, and that silent fans be for extracting the vitiated air instead of coke fires as at present.

ALUMINIUM WORKS AT FOYERS.

AN Inverness correspondent of the *Scotsman* writes:—An Aluminium Company has been floated, which is to take clay containing that mineral from Ireland to the side of Loch Ness through the Caledonian Canal. Great electrical power is required to extract the mineral from the clay, and it is proposed to construct extensive works in the Valley of the Foyers, in order to generate the necessary force. One of the lochs is to be raised 60 feet and another 30 feet; a public road along the side of Loch Faraline is to be submerged, but it is understood a good road will be substituted. The dammed-up waters are to be conveyed to Loch Ness side, where the necessary turbine and other machinery for generating electricity will be constructed. The calculations of the promoters will involve, it is stated, the necessity of withdrawing the water from the Foyers during the summer and autumn months. A meeting of the Inverness District County Council has been convened for February 22 to consider a letter from Mr. Charles Innes, solicitor, Inverness, on behalf of the British Aluminium Company, asking that a proposal to submerge certain public roads and substitute others be sanctioned.

SUN INSURANCE COMPANY.

THE Yorkshire headquarters of the Sun Fire and Life Assurance Company have just been removed from East Parade, Leeds, to 15 Park Row. The building in Park Row has not been specially erected, for it was quite a modern stone structure. Nevertheless it has been subjected to a complete overhauling internally. Behind the front portion of the premises an important addition has been made, and the suite of offices has been practically doubled by the building of a substantial pile, with a frontage to Basinghall Street. The two blocks are connected with each other by a wide corridor on each floor. In place of the old narrow stairs a large central staircase has been provided, up the centre of which there is a hydraulic lift, without which no commercial building is nowadays complete. It goes without saying that no expense has been spared in imparting an attractive appearance to the various rooms and corridors, and the result is that the whole forms one of the finest blocks of offices in the city. The architectural work has been carried

out from designs prepared by Messrs. Chorley & Connon, Leeds. Mr. Windsor Thorp, architect, Commercial Street, Leeds, was entrusted with the task of designing the fittings for the rooms occupied by the insurance company itself. The office itself is supplied with richly designed polished furniture. The bulk of the woodwork here exposed to view is of the hardest and best quality of Burmah teak, a wood well known to be about the least liable to shrinkage, or to be affected in any way by variations in temperature. The internal woodwork, where not in view, is either of mahogany, canary wood, or sequoia, which have also been selected for their peculiar individual advantages. The external woodwork in the private rooms of Mr. Roberts and Mr. Wootton is of the best figured Riga wainscot oak, fumed and wax polished. The distinguishing features of the fittings are their elaborate and rich treatment as regards design, materials and carving, and the excellence of the workmanship. They have been made by Messrs. R. Garnett & Sons, Warrington and Penketh, under the immediate supervision of Mr. Thorp. All the carving will bear the closest scrutiny, not only because of the beauty of the designs, but because of the manner in which the designer's ideas have been brought out to the full. As examples of fine carving, some of the panels in the general office will be hard to beat. Special attention may be drawn to that over the entrance door, and to the one in the centre of the overmantel opposite. The latter is cut in deep relief, and illustrates the "mark" of the office, which was discovered comparatively recently in the vaults of the Sun office amongst some old papers. It bears the date January 13, 1711, and was for policy No. 838. In this room are the panels of fibrous plaster designed by lady students attending the Leeds School of Art. The ceiling in the front office is also worthy of particular mention. It is a very fine example of plaster-work, the design being very intricate and very pretty. The building is lighted throughout with electricity.

The work, apart from the furniture, has been carried out by the following contractors:—The dial and art metal work, Messrs. Soutter & Sons, of Birmingham; masonry and brickwork, Messrs. Nicholson & Sons; carpenters and joiner's work, Messrs. J. Tomlinson & Sons; plumbers and glazier's work, Mr. J. Lindley; plasterer's work, Mr. T. Moore; slater's work, Messrs. Sharp & Harper; painter's work, Mr. C. Fenton; lift, Mr. R. Middleton; faience work and tiles, Messrs. Webb Brown & Co.; book lift and lift enclosure, Mr. A. Dougill; modelling, Messrs. Thewlis & P'Anson; electric lighting, Mr. Wilson Hartnell; gas engine, Messrs. Crossley Bros.; iron

ELECTRIC EXPLOSIONS.

THE report of Major P. Cardew, the Board of Trade inspector who recently held an inquiry into the two explosions which occurred in the electric-light conduits in the Euston Road, on December 29, has been presented. He says:—"After careful consideration of the evidence, and of my own investigations, I am of opinion that the explosions were caused by the firing of a mixture of coal-gas and air by an electric spark. I account for the presence of coal-gas by leakage from the mains of the Gas Light and Coke Company at one or more points in the vicinity of the electric-light conduits, percolation of the escaped gas along the lines of gas and electric mains, which are parallel and in close proximity, where the soil has been frequently disturbed; and entry into the electric conduits and boxes wherever small openings may exist, which, from the construction and materials used, will certainly be the case at many points. The gas would naturally percolate into the open space provided by the electric-light conduit, and this would be facilitated, to some extent, by the small amount of heat produced by the electric current in the mains. It is probable that, since the general adoption of wood pavement and other forms of pavement, which prevent the escape of gas from the soil directly into the open air, the danger of its percolating into underground chambers has been materially increased. The means provided by the St. Pancras Vestry for the immediate escape of any gas from their conduits are, in my opinion, totally inadequate, and even a slight leakage of gas into the conduits would be likely to accumulate until the proportion of gas in the air reached that necessary to form an explosive mixture. The occurrence of an electric spark was, I think, probably a result of formation of salt incrustation on the insulators. This no doubt acts, to some extent, as a conductor, and if a piece break away, a small spark would very likely be caused.

"The Vestry of St. Pancras should lose no time in removing the two existing causes of danger which I have indicated, viz. the possibility of an accumulation of coal-gas in their conduits, and that of the occurrence of an electric spark at their bare conductor mains. This system of mains and conduits was selected, I believe, mainly for economical reasons, and no

doubt it has advantages in this respect, but these economical advantages must not be reaped at the expense of the safety of the public using the streets. The Vestry were, I understand, advised by Professor Robinson, after the serious explosion which occurred on January 12, 1894, in a street box in Endsleigh Gardens, close to the position of the recent explosion, to carry out a system of efficient ventilation wherever possible, and in a report on this accident which was forwarded to the Vestry by the Board of Trade I also advised this, and further recommended that, where possible, two small chambers should be substituted for the large ones at present in use as street boxes, and that the low insulation of the negative main, which was then, as now, a very noticeable defect, should be remedied. Sufficient attention has not, I consider, been paid by the Vestry to these recommendations. It was stated by Mr. Baron, the chief engineer, at the inquiry, that there are only eleven ventilating pipes and three ventilating covers to street boxes for a total length of $6\frac{1}{2}$ miles of conduit, and the nearest ventilating pipe was about 300 yards from the scene of the explosion. None of the large street boxes have, it appears, been divided into two smaller ones, as suggested by me, and the attempts made to remedy the serious leakage on the negative main have not so far been successful. I am of opinion that the Vestry should immediately provide a thorough system of ventilation, or means for the immediate escape of gas from their conduits and street boxes, should reduce the empty space available for accumulation of gas in their street boxes as far as possible, and should carefully guard against the dangerous formation of an incrustation of salts on the insulators of the negative main by frequent inspection, and by protecting these insulators against drip from the condensation of moisture on the iron lids of the street boxes."

INSANITARY PROPERTY IN LEEDS.

How to deal with the insanitary areas of the city, says the *Leeds Mercury*, is one of the questions now uppermost in the minds of the leading officials and members of the Leeds Corporation. Correspondents have urged the desirability of dealing with individual houses rather than with whole areas, removing an obstructive building here and taking down dilapidated property there, and in this way letting air and light into a district without entirely demolishing the existing property. A scheme of this sort in regard to the large area

SHORLAND'S PATENT COMBINATION OPEN FIRE-PLACE MANCHESTER STOVE

Made in various Designs and Sizes, with Tiled or Iron Sides, Single or Double Fronted, and with Ascending or Descending Smoke Flue.

Very largely used in HOSPITAL WARMS, for which the down-draught arrangement, as now shown, is specially suited.

between Quarry Hill, Marsh Lane and the Lady Beck was placed before the sanitary committee in 1890 by the present medical officer of health. His suggestions were made in consequence of an outbreak of typhus fever in that district. By that scheme it was proposed to run a new street through part of the area and here and there to remove obstructive houses, so as to let the air into the back yards and generally improve the district. The rough estimate of the cost of such an improvement was laid before the committee at the time, but the medical officer thought it necessary also to point out "that great as would be the advantage of letting light and air into this unhealthy neighbourhood, the authorities would still leave houses of a very inferior type, most of them, however, well drained, and so far as their present structure would admit, sanitariously good, but small, dirty, redolent of odours of generations." Taking this into account, the medical officer suggested it might be wiser to consider the question of the removal of the whole area. For something less than 800,000l. they might clear away entirely this nest of disease, although, of course, the question of providing accommodation for the displaced inhabitants would remain. The alternative suggestions of the medical officer of health were referred to the city engineer, who reported again to the sanitary committee, under whose consideration the matter has been ever since. If the sectional plan is adopted, only one portion of the area will be dealt with at a time, and the Corporation will be compelled by the Local Government Board to provide the necessary accommodation before going on with the next section. If, however, instead of dealing with the area in this way, under the first part of the Housing of the Working Classes Act, the authorities were to adopt the first suggestion of the medical officer of health, and to deal piecemeal with a few houses here and a few there, this could be done under the second part of the Housing of the Working Classes Act; and as no provisional order would be required, the Corporation could proceed with their displacements without providing any fresh accommodation. The first part of the Act of 1890 deals with large insanitary areas such as the one mentioned; the second enables a sanitary authority not only to get rid of individual houses unfit for habitation, the houses which, though they might not in themselves be unfit, yet might be regarded as obstructing the passage of air and light to others, and thus rendering them unsuitable for dwellings; but this part of the Act also, enables authorities to deal with such small areas as the one in Camp Field, and with other districts too limited to require the putting into force of

the first part of the Act. The mode of dealing with these smaller areas under the second part of the Act is considerably less cumbersome than the method required under the first part. Even the provisional order can be dispensed with if the property-owners and the Corporation have agreed as to matters of price. The advantage of dealing with a large district such as the one already named in the North-East Ward is that the Corporation are enabled not only to pull down buildings which no one for a moment would regard as proper places for human habitation, not only to remove obstructive dwellings which prevent the circulation of air through courts and alleys, but to get rid, if necessary, of whole streets of habitations, and to open out wide streets and introduce fresh air and sunshine into the slums. The great fault in the original laying-out of the insanitary area in question seems to have been the utter disregard paid to the inhabitants' requirements of air and light. Pulling down a house here and there would do a certain amount of good, but it would still leave large numbers of houses scarcely fit to be used as dwellings, and it would perpetuate the irregular, crooked streets along which the air cannot freely pass. The acquirement by the Corporation of sections time after time would not necessarily mean that the whole of the houses in that section would be pulled down. This, however, it would mean, that no new house would be erected on the old street lines. New streets would be planned at once, and gradually the whole of the property in the section would be removed and replaced by more modern and healthier dwellings.

THE PAINTING OF HAMMERSMITH BRIDGE.

THE following letter has appeared from Mr. W. Dudley:—

As the contractor who undertook this work in 1888, may I be permitted to state the true facts, as distinguished from the imaginary ones put forward on behalf of the works committee of the County Council?

1. All my materials as used in connection with the painting, such as white lead, raw and boiled oil, turps, varnish, gold and driers, were examined and approved by the Board of Works.

2. Mr. Sydney Webb alleges that "the work was not done in the winter." This statement is untrue, the fact being that I commenced the work in September 1888, and completed it in 1889.

3. I was compelled to put up scaffolding for the whole of the

bridge at the same time, and give one coat of paint throughout before commencing the second coat. The same fact also applies to the third coat, and also to the gilding and varnishing. So much care was exercised in connection with the scaffolding that not a single man employed received even a scratch throughout the whole of the job.

4. The whole of the materials used were of the best quality, and I am prepared to prove that they cost from 15 to 20 per cent. more than the present market price.

5. With regard to the wages paid, no painter received less than sevenpence-halfpenny per hour, most of them eightpence, labourers sixpence, scaffolders sevenpence. Most of the men employed had worked in the decoration of Bermondsey Town Hall. That hall is as good now as when finished. It did not, of course, require an experienced painter to rub down the ironwork.

6. I personally superintended the whole of the work, and everything was done to the entire satisfaction of the Board of Works.

7. By all means let the works committee have a fair trial, but is it not most unjustifiable on the part of the representatives of that committee to excuse their own incompetency and extravagance at the expense of one who did the work in a satisfactory and workmanlike manner, at hundreds of pounds less than the amount expended in connection with the recent painting of the bridge?

8. The apologists of the committee should understand that I have to get my living by hard work, and not by delivering addresses to endeavour to justify extravagant and unjustifiable expenditure.

MANCHESTER SOCIETY OF ARCHITECTS.

COMBINED warming and ventilating was the subject of a lecture delivered by Mr. J. D. Sutcliffe before the Manchester Society of Architects on February 5. The lecturer contended that the warming effect of an open fire upon a room is not obtained direct from the rays of heat, but from their reflection from the various material objects with which they come into contact, otherwise that the sole effect of the fire is to draw cold air into the room, especially along the floor. Much more warmth was derived by direct radiation from common stoves, pipes and coils, but in all of these cases there is no ventilation, the same air being breathed and warmed over and over again. Indirect radiation he described as obtained by

the 'passing of air over heated surfaces and thence into the room, always securing some ventilation as well as warmth. This combined warming and ventilation, when provision is made for supplying fresh air and simultaneously discharging vitiated air. He instanced the American system of Messrs. Smead, which is in operation at the Friends' Meeting House, Birkenhead; architects, Messrs. Grayson & Ould, of Liverpool. The Friends' Meeting House, Scarborough; architects, Messrs. Malcolm, Start & Rowntree, of Glasgow. It appears that results are satisfactory in both places, but that system does not admit of proper provision for filtering the air where the conditions of the atmosphere render that necessary.

The Plenum system, which is the best for large buildings, is always associated with mechanical force, and admits of any filtering arrangements. A fan draws in external air through a filter, and at the same time propels it through heating apparatus, whence the filtered and warmed air is driven into main and branch ducts that terminate in the rooms to be warmed. Entering above the heads of the occupants the warm air necessarily rises at once to the ceiling, where it spreads, cools and consequently descends, eventually passing out at the floor level by exit ducts there provided. Dusty and other vitiated air is thus prevented from rising, and the weight of the respired carbonic acid gas accompanies and aids the descent. Experience proves that the warmth so derived is agreeable and equable, and the system prevents inward draughts or the entry of any contaminated atmosphere from outside, such entry being often experienced where mechanical force is applied solely for drawing foul air out. The system provides for entirely renewing the air of the room at any desired rate up to ten times an hour. The Plenum system is in operation (or it will be used when the buildings are complete) in Temple Chambers, Manchester (ninety separate offices), designed by Mr. Edward Hewitt, one of the honorary secretaries. GILBERT WOOD & CO., 175 STRAND, LONDON, W.C.

one of the smallest in England; it was the first school in which the system was applied. Other schools are also satisfactorily warmed and ventilated by mechanical means, and innumerable factories, mostly upon the exhaust system, 25,000 Blackman fans being employed, capable of moving an aggregate of air averaging 800,000 tons per hour.

In Temple Chambers (the first building in which the system was completely applied) not one of the ninety rooms has a fireplace, the whole building being well warmed by one coke fire in the basement. It has been theoretically inferred that air, when treated as described, must be unhealthily dry, but repeated tests prove the presence of ample moisture.

In the Pendleton School, before it was opened, tests were applied which proved that the warming attained to 58 deg. when the temperature was below freezing-point outside. During the same period there was exhibited another development of the great utility of the system which, being got into operation as soon as the windows were in, thoroughly dried and made the whole place quite ready for occupation some weeks and perhaps months before it would have been as safe by any other means.

This school is the first completed one in Manchester and Salford district. The lecturer hoped Manchester would not be long behind their neighbour Salford.

Salford Technical School is a good illustrative example of a double-duct arrangement carrying cold and warm air separately. The additional facilities it gives for regulating temperatures are very highly appreciated. The supply of fresh air is equal to 3,000 cubic feet per hour for each student, providing for complete renewal four times an hour in the drawing and similar rooms, and ten times an hour in the chemical laboratories.

A hearty vote of thanks was passed to Mr. Sutcliffe.

THE CABLING OF EDINBURGH TRAMWAYS.

A MEETING of the Lord Provost's committee of Edinburgh Town Council was recently held to consider the cabling of the tramways in the city. The burgh engineer (Mr. Cooper) submitted a plan of existing and new routes which might be worked by cable, along with a report on the subject. The total length of the existing double-line tramways in Edinburgh, exclusive of the line from the Post Office to Jock's Lodge, is 9½ miles; the length of the single line is 2·86 miles. In Leith

the double lines extend to 1·838 of a mile, and the single lines to 0·279 of a mile. The routes which he suggests for cabling are those on which the traffic is sufficiently heavy to justify the constant tear and wear common to the cable system, and he recommends that Edinburgh and Leith should be treated as a whole. He mentions two central power stations for Edinburgh—one in the neighbourhood of Tollcross and the other at the existing tramway depôt at Shrubhill, which is nearly seven acres in extent, and is the property of the Corporation, and which is large enough for all the purposes of the services. Mr. Cooper proposes that the first route should start from Shrubhill, travel into Leith, and cover Bernard Street and Junction Street, but that the Newhaven and Seafeld branches should continue to be worked by horses. The second route would also begin at Shrubhill, and, coming up Leith Walk, go south by the bridges and Clerk Street to the city boundary at Craigmillar, the existing line being extended to that point. Other extensions mooted were a line from Broughton Street, East Claremont Street, Broughton Road and Bonnington Road to the present line at Junction Street, and one from Leith Walk along London Road and Easter Road; but as it would be some time before these would prove remunerative, they are not put forward as practical proposals in the meantime, although they could also be propelled from Shrubhill. The line from Waterloo Place to Portobello would continue for the present to be worked by horses. The first route to be propelled from the Tollcross station would be that going north from Tollcross along Lothian Road, east by Princess Street to the Post Office, back to the Haymarket, and along the Dalry Road to the junction with the Colinton Road line at Polworth Terrace. The branch line from Haymarket to Coltbridge would in the meantime continue to be worked by horses. From the station at Tollcross the cable would travel by Leven Street, Bruntsfield Place and Morningside Road to the city boundary near the Braid Hills. On the cross route from Newington to Morningside serious difficulties in the working of the cable would be presented by the many sharp angles which occur, and it is suggested that the route might be straightened by being carried along Strathearn Road and Strathearn Place to Churchill. That cross route would be worked in conjunction with the cable from Tollcross to the Braid. The Gimmore Place route having only a fifteen minutes' service, and being a single line, the burgh engineer does not consider that cabling is urgent, and he thinks the route might be left alone. The

"OPTIMUS" MAGIC LANTERNS SUITED FOR DRAWING ROOM AND LECTURE HALL.

Each Magic Lantern is efficient for exhibitions. The Lens gives crisp definition, being a superior Achromatic Photographic Combination with rack and pinion. It is fitted to a telescopic lengthening tube, so gaining increased focal accommodation. The Condenser is composed of two plano-convex lens of 4 inches diameter. The refrugent lamp has 3 wicks, yielding brilliantly illuminated picture. Each is complete in box. Pairs for dissolving arranged in one Box at same prices. Lever Dissolver, 8s. 9d.

were kept in closed vessels for some days, the growth of bacteria was much more rapid in some than in others. No bacteria associated with infectious diseases could be found in any of the specimens examined, although they were carefully searched for. The chemical and bacteriological examinations are in substantial agreement; both methods show that there is no sewage contamination of the water-supply.

THE INSTITUTION OF CIVIL ENGINEERS.

At the meeting of this Institution on Tuesday, the 29th ult., Mr. J. Wolfe Barry, C.B., vice-president, in the chair, the paper read was on "Boiler Explosions," by Mr. William H. Fowler, Wh. Sc., Assoc.M.Inst.C.E.

The author referred briefly to the theories, such as "deferred ebullition," "disassociation of water," "spheroidal condition," which were propounded to account for such explosions. He showed that it was the hot water rather than the steam in the boiler which formed the source of destructive energy, and, with a view to illustrate the amount of stored energy available in the event of explosions, pointed out that it was equivalent in the case of a Lancashire boiler 8 feet in diameter by 30 feet in length, at a pressure of 150 lbs., to the work expended in lifting the structure to a height of nearly 8,500 feet, roughly speaking equal to the explosion of 1,700 lbs. of gunpowder.

In regard to the causes of boiler-explosions, there was nothing occult or mysterious. They could, as a rule, be traced by patient investigation to the operation of simple and well-known facts. Thus when a boiler-shell was normally in a state of high tension, if once a rupture took place by the action of static stresses on a locally weak spot, the stored-up energy was capable, not only of tearing the boiler to pieces, but of producing all the other destructive effects observed in connection with such disasters.

Prominent among the principal causes of explosions was the corrosion of the boiler-shell. This was sometimes internal from the action of corrosive feed-water, and sometimes external as a result of dampness in the brickwork settings. This latter species of corrosion was much accentuated by the defective manner in which boilers were often set. The bearing surface of the brickwork on which the boiler rested was often much too wide and of such a character as to afford a convenient resting-place for the lodgment of moisture, with the result that corrosion was set up and went on unseen and un-

suspected. The safeguard against the operation of external corrosion was a suitable design of boiler-setting, and the adoption of periodical inspection, to facilitate which the flues should be so arranged as to be easily accessible.

The peculiar defect known in steam-boilers as grooving or channeling was the result of a combination of corrosion and of mechanical action, and was met with under a variety of circumstances; the mechanical action due to alternations of steam-pressure, which caused local fretting, and by splitting off the scale and oxide as fast as it was formed, much accelerated the corrosive action of the water. Instances of this kind were explained and illustrated in the flat ends of Lancashire and Cornish boilers, as well as in the fireboxes and uptakes of vertical boilers. In the case of locomotives the grooving met with was of a very specific character; it was confined, almost invariably, to the edges of the overlaps of the longitudinal seams, and to those boilers in which these seams were made with an overlap joint. No case of grooving had come under the author's notice where the joints in the barrel were of butt straps so as to preserve the true circular form. The reasons why this defect was more pronounced in locomotives than in other boilers were twofold. In the first place, the barrel was of small diameter, and thus the use of the overlap joint caused a relatively greater deflection from the circular form; and in the second place, this type of boiler was liable to sudden and large fluctuations of pressure, the mechanical action from which was further intensified by the jolting such boilers experienced in their daily work.

Some explosions had their origin in the stresses arising from expansion and contraction due to the action of the fire. This was especially the case in boilers of the externally fired class, of which the plain egg-ended type might be taken as a typical sample. In this type any sediment or dirt in the water naturally settled to the bottom over the fire and led to overheating, and when fed with cold water a long strip of the plating from end to end was suddenly chilled, causing serious straining at the ring seams. These were of so serious a character that although the ring seams were theoretically double the strength of the longitudinal ones, cases frequently occurred in which such boilers were rent in twain circumferentially and shot in opposite directions without giving the slightest preliminary warning.

In the ironworks districts a peculiar form of egg-ended boiler, set vertically and having a central flue with two or four radiating branch flues, was often used in connection with

puddling furnaces for utilising the heat in the waste gases. This boiler had all the initial defects of the horizontal egg-ended one; and had been responsible for some of the most disastrous explosions on record, owing to the fact that, when such a boiler gave way, the contents of the surrounding puddling furnaces with which it was connected were scattered like a shower of Shrapnel upon the crowd of workmen engaged. The presence of the internal flues necessitated shells of large diameter and the consequent use of thick plates. This was inimical to the passage of heat, while the intense character of the flames which impinged upon the plates accentuated the trouble.

A common source of boiler-explosions in the past had been the practice of cutting large openings in boiler-shells, without providing compensating strengthening-rings. The result of cutting large openings in the shell was to accentuate greatly the stress at the edge of the hole on its longitudinal diameter. The exact distribution of the additional stress in consequence of the cutting away of the material was not known, but it was much greater at the edge of the hole than was generally supposed. Large domes were sources of weakness in a boiler-shell, even if the hole which permitted access to them were of small diameter.

Overheating from shortness of water was a common cause of boiler explosions, but the operation of this cause was different from the reason formerly assigned to it. Explosions were not the result of turning cold water on to red-hot plates. What took place was that the overheated plates became gradually softened, with the result that they bulged downwards and were rent at the ordinary working pressure; explosions of this kind were of a relatively mild character. As a safeguard the use of duplicate water-gauges was recommended, as well as a low-water safety-valve and a fusible plug, while the feed-pipe should be at such a level as to prevent any risk of the furnace-crowns being laid bare through the water syphoning back owing to a defective check-valve.

Many explosions arose from excessive pressure in consequence of the defective action of the safety-valve. This might occur in a variety of ways, but the type of valve loaded with a spring-balance was the most prolific source. This arose from the facility which the valve, as it was ordinarily fitted, provided for overloading by merely turning the thumb-nut, while it also permitted of tampering in many other ways. The practice of grouping the safety-valve and stop-valve on a common outlet was to be deprecated on account of the risk of the outlet being

plugged in the case of the boiler being under repair. Two disastrous explosions had been traced to this cause. Each fitting should have its own outlet, and valves of the dead-weight type were preferable to those with levers. If springs were necessary they should be direct-acting.

Explosions sometimes arose from faulty material and construction. As a result of using iron of poor quality with punched holes, incipient flaws were occasionally set up in the seams, and several cases had occurred in which these inherent defects were so situated as to forbid detection when the boiler was put together, and were only revealed by the explosion. These defects showed the value in connection with new work of a careful hydraulic test.

PATENTS.

[This List of Patents is compiled specially for this Journal by Mr. G. H. Rayner, of the firm of Rayner & Co., Consulting Patent Agents, 37 Chancery Lane, London, W.C., from whom all particulars and information relating to Patents may be had gratuitously.]

APPLICATIONS FOR PATENTS.

- 1365. Arthur Calvert and William Durant, for "Improvements in means for securing slates in position upon roofs."
- 1450. George B. Pearson Wallis and Jabez Gibson, for "Draught excluder for doors, windows and the like."
- 1522. Alfred Conway, for "An improved chimney-pot."
- 1640. Henry Bennett, for "Draught excluder for the bottom of doors."

THE
Architect and Contract Reporter.

NEW READING CASE.

To Librarians of the Public Libraries and Reading-rooms.—A new handsome Reading Case can be supplied at a nominal charge of 2s., by post 2s. 6d., on early application to the Publisher, 175 Strand, W.C.

SPECIAL NOTICE TO THE TRADE AND OTHERS.

[Extract from a lecture on Architects' Libraries by Professor T. Roger Smith, F.R.I.B.A., at University College, October 10, 1893.]

"Lastly, let me recommend the back volumes of the professional journals. In the course of years all sorts of architectural topics come up in the public press and before the professional societies, and if you hunt through the indexes of these publications when you are seeking for information which eludes you in books, you will often be rewarded."

There has been a considerable demand for the back numbers of *The Architect* during the last three or four months, which we have no doubt has arisen from the remarks made by Professor Roger Smith, as contained in the above quotation; but the consequence has been that our stock of back numbers is getting very low, and consequently, in future, the charge for back numbers of previous date to January 12, 1894, will be 6d. each.

A few of the back volumes may still be had, price 12s. each.

EDITORIAL NOTICES.

The authors of signed articles and papers read in public must necessarily be held responsible for their contents.

No communication can be inserted unless authenticated by the name and address of the writer—not in every case for publication, but as a guarantee of good faith.

Correspondents are requested as much as possible to make their communications brief. The space we can devote to Correspondence will not usually permit our inserting lengthy communications.

TENDERS, ETC.

* * As great disappointment is frequently expressed at the non-appearance of Contracts Open, Tenders, &c., it is particularly requested that information of this description be forwarded to the office, 175 Strand, London, W.C., not later than 5 P.M. on Thursdays.

VARIETIES.

THE annual dinner of the Birmingham Association of Mechanical Engineers has just been held. In addressing the assemblage, Mr. Jesse Collings, M.P., said he hoped it would always remain a cardinal point with the Birmingham City Council when it wanted professional advice on any occasion—whether law, engineering or anything else—to get the very best they could buy. The only thing that frightened him was evidence of cheese-paring in buying professional advice.

AT Perth a movement has been set on foot with the view of constructing a new bridge across the river Tay.

AT the quarterly meeting of the Warwick Town Council, Alderman Fosbery moved a resolution that it was desirable to construct a new road across the Pigwells to the Saltisford, to demolish the insanitary houses in that neighbourhood, and to erect healthy dwellings in their place, and that a committee be appointed to consider a scheme for this purpose. The resolution was carried and a committee appointed.

THE Doncaster Board of Guardians have decided to purchase a site of 31 acres on which to erect a new workhouse.

AT the quarterly meeting of the Evesham Town Council, the Mayor (Alderman Hunt) said the Council would be glad to hear that at a recent fire the new voluntary fire brigade was found to be competent in the discharge of its duties.

TRADE NOTES.

AT the meeting of the Liverpool City Council the tender of Messrs. J. Paterson & Son, for the new Library and Technical School, was accepted at 10,399/.

MR. T. FREEMAN, of 200 and 202 Phoenix Street, St. Pancras Station, informs us that he has been appointed for seven years the sole agent for the sale of the whole of the building stone quarried at the "Beggar's Well" and the "Battlestead" quarries, the property of Mr. John Fielding, of Alton, Staffordshire. Messrs. Giles, Gough & Trollope, of Craven Street, have specified the "Beggar's Well" stone in the construction of the extensive asylum that the Staffordshire County Council are about to erect at Cheddleton; and the contractors, Messrs. William Brown & Son, of Salford, have given instructions for about 40,000 cubic feet to be quarried.

Works very FREELY and covers EVENLY. It only requires thinning with TEPID WATER. Its covering properties are nearly half as much more than any other Paints or Distempers.

ANTHYDOR COMPOUND & GENERAL PAINT CO.

LIMITED,

47 VICTORIA STREET, WESTMINSTER, S.W.

The Roman Catholic church of St. Giles, Cheadle, the gift of the Earl of Shrewsbury in 1846 at a cost of 120,000*l.*, from the designs of the late A. W. Pugin, is built of this stone; also that of St. Giles, Newcastle-under-Lyme. Hitherto but little has been sent to London. The railway rate will now, however, enable the "Beggar's Well" to compete with Mansfield & Dumfries. I shall be pleased to give any further information if desired.

WE hear that the Self-Lock Roofing Tile Co. have taken new and more extensive premises at Bow.

THE new workhouse infirmary, Pontefract, is being warmed and ventilated throughout by means of Shorland's patent Manchester stoves with descending smoke-flues and patent Manchester grates, the same being supplied by Messrs. E. H. Shorland & Brother, of Manchester.

WE are informed by the Anaglypta Co., Limited, that their arrangements to manufacture at Darwen are now complete. On and after Monday, February 11, all orders will be executed from their works at Darwen, and all communications to reach them on and after Monday, February 11, should be addressed to "The Anaglypta Co., Limited, Darwen." The experience gained in establishing the business has enabled them to design entirely new works with the latest improvements and increased facilities for the manufacture and despatch of goods.

AN AUSTRALIAN EXAMINATION PAPER.

THE following papers were set for the last Associateship examination of Royal Victorian Institute of Architects:—

Styles of Architecture.

1. Name the five orders of classical architecture and give their principal proportions and leading features, and illustrate the descriptions with sketches.

2. Explain and illustrate by sketches the meaning of the following terms:—Billet, cortile, flèche, loggia, carona, telamones, systile, sgraffito.

3. Give briefly the leading characteristics as to plan, construction and ornament of the Greek, Roman, Romanesque and Gothic periods and give rough sketches.

4. Write a brief description of two of the following buildings, giving the style and dates and names of their architects:—Church of St. Vitale at Ravenna, Cathedral of Pisa, Cathedral at Florence, Library of St. Mark's at Venice.

5. Write a short description of one only of the following buildings:—Salisbury Cathedral, Henry VII. Chapel, Westminster.

6. Sketch the differences in plan and section between the basilican form of churches and the Gothic cathedrals of the late twelfth century.

7. Give a short account of some building designed by Palladio, Inigo Jones and Philibert de Lorme.

8. Name a typical Romanesque church in Germany or France, its date and particular features.

9. Name some representative French cathedral and describe it.

10. As to the accompanying ten photographs, give in each case (a) the style, (b) the county or locality, (c) the order, period or century, (d) explain upon what details or feeling you base your opinion, (e) if you recognise the building give what particulars you can in addition.

Mouldings, Features and Ornament.

1. Drawn to a scale of $\frac{1}{2}$ inch to a foot a Greek Ionic column showing cap and base, lower diameter to be 3 feet.

2. Draw to a scale of $1\frac{1}{2}$ inch to a foot the entablature carried by column above, and write against the various portions thereof the name each bears.

3. Describe the use of the human figure as a decorative feature in Greek buildings, and name the parts of a building in which such decoration was usually put.

4. What are the leading characteristics of Romanesque mouldings, and from what sources are they derived? Illustrate with sketches to large scale.

5. Describe and illustrate by sketches to large scale the following terms:—Gargoyle, flèche, battlement, dormer, finial, sedilia, machicolation, peristyle, crocket and ballflower.

6. A doorway is to be formed in a stone wall 3 feet thick, the opening to be 10 feet wide, drawn to scale of 1 inch to a foot, the arch-mould and plan of jamb (a) in the thirteenth-century Gothic style, (b) in the fifteenth-century Gothic style.

7. Sketch a Gothic buttress, also a flying buttress, and describe the origin and use of the latter. State the period which your sketches represent.

Shoring and Sanitary Science.

1. It is proposed to convert the front of the warehouse, shown in drawings A, into a shop, and to put a cellar extending back 24 feet and the full width of the building and 10 feet high

from floor to ceiling. Describe in order each operation necessary to carry out this work, and illustrate by pencil sketches to scale.

2. When rain-water from the roofs has to be conveyed to the sewers, what precautions must be taken to prevent egress of drain air from the down pipes in very dry weather?

3. As to water-closets. Describe and sketch some of the best types, and state their relative advantages and disadvantages.

4. How are automatic flushes produced? Describe and sketch some of the apparatus, and state under what circumstances their employment is necessary or advisable.

5. What is meant by the term "seal"? What should be the amount? How is it liable to be diminished? How can the latter be avoided? Give rough sketches.

6. Fig. 6 shows a plan of a building with stables at rear, and the w.c.'s, sinks, bath, &c., are marked. Sketch on the plan the various drains, waste-traps, &c., you would adopt, and describe and sketch the various fittings, connections, &c.

7. As to underground tanks, what special precautions must be taken in their construction and in the arrangements of supplies and overflows to avoid pollution of the water?

8. Fig. 8 shows plan and section of a country hall which is detached 6 feet at sides from adjoining buildings. You are required to sketch to scale the exit openings and ventilation you would adopt to comply with the Public Health Regulations.

Nature, Property and Application of Materials.

1. What is the term hydraulicity as applied to limes and cements?

2. What are the constituents of limestone (a) which do not produce hydraulicity; (b) which do produce it?

3. What are the materials used in the suitable proportions for good cement concrete?

4. Describe the principal stones that have been used for building purposes in Melbourne, and mention their relative advantages and defects and any special purpose for which they may be suitable.

5. What are the principal woods used in carpenters and joiners' work in Melbourne? Describe their peculiarities and for what special purposes they can be used with advantage.

6. In connection with painting, explain the meanings of the following terms, and give examples of each:—"Base, vehicle, solvent, drier."

7. For what purposes is concrete usually employed in

buildings? Mention several, and describe the operations of each.

Principles and Practice of Construction.

1. Design a floor having an area of 20 feet by 20 feet and unsupported by columns, but with iron girder construction, and to carry 100 tons equally distributed. Scales:—General drawings 4 feet to 1 inch, detail 2 feet to 1 inch. Submit full calculations for above.

2. Draw a cross section of a Gothic roof for a church nave 30 feet clear in width, and to a scale of 2 feet to 1 inch.

3. Show the construction of a waterproof brick cellar 15 feet by 15 feet, and having a depth from floor-line of ground floor about to surface of cellar floor of 10 feet, and put descriptive notes on drawings. Scale 2 feet to 1 inch.

4. Show details of slate roofing, with lining and battens and eaves, and from eaves to ridge; rafters 10 feet long. Scale 1½ inch to 1 foot.

5. Make detail drawings to a scale of 1 inch to 1 foot of a window 7 feet by 3 feet in an 18-inch brick wall, and with panelled inside linings and external louver shutters.

6. Describe how cement concrete for footings of a heavy building should be formed and put into trenches and prepared for receiving brick foundations, also lime concrete for an ordinary building.

7. Describe the laying of floor tiles and bed for same.

Drawing and Designing, Planning and Arrangements.

1. Subject for design—A band pavilion of the dimensions figured on the skeleton plan in margin where AAA represent the posts; the inner dotted line represents the outer circumference of the brick or stone foundation-wall. The line BB represents the extreme size of the floor, &c., the outer dotted line, the extreme projection of the eaves. Height from surface of ground to floor to be 3 feet; height from floor to eaves to be 12 feet. The construction to be of wood except foundation-wall, which is to be of brick or stone, and ties of roof principals which may be of iron. The steps to be of wood. The roof to be open with central lantern or cupola. The material for the roof's covering to be at the option of the candidate. The following drawings are required:—Plans for floor and roof, elevation, sections on the square and on the diagonal. The above to be to ½ inch or ¼ inch scale, also details of the various parts to ½ inch or 1 inch scale.

2. Fig. 2 is the copy of the aspect compass from Kerr's "English Gentleman's House" indicating the character of the weather and extent of the sunshine, &c., for various aspects in

"MANCHESTER" DYNAMO.

England. Draw a similar compass for Melbourne as nearly as you can judge.

3. In planning a study in (say) a clergyman's house, what considerations should guide you in determining the best positions for door, windows and fireplace?

Write a specification for the carpenters' and joiners' work of the pavilion you have just drawn; also of the trade required for roof covering you adopt.

Quantities and Estimates.

1. What are the standard measurements of the following work:—(a) rubble, (b) ashlar, (c) floor timbers and flooring, (d) asphalt with concrete underneath, (e) concrete in footings, (f) timber in roof principals?

2. In quantity surveying explain the meaning of the following terms, and give example of each:—Quantities, squaring, abstracting, billing, schedule.

3. In sketch plan of wood addition given below, take out the quantities and material in walls and roof, and show method of calculating same. Walls, 3 feet by $1\frac{1}{2}$ inch, studs 16 inches centres; plates, 4 inches by 2 inches; blocks, 4 inches by 4 inches, R G 3 feet centres; roof, lean-to constructed with $5\frac{1}{2}$ inches by $1\frac{1}{2}$ inch rafters, 16 inch centres and covered with corrugated iron.

Professional Practice.

1. State in detail the usual terms of payment to contractors during progress of works and on completion, and distinguish clearly between the effect of the different forms of certificate.

2. In the case of there being a discrepancy between the drawings and specification, what course is usually followed, and what are the rights and duties of the architect, owner and contractor respectively under the circumstances?

3. In the case of an owner requiring large extra works on a contract, what steps would you take to have same executed, and what do the contract conditions provide for the protection of the owner and contractor respectively?

4. What are the rights, duties and liabilities of the architect of a building under the contract?

5. Into how many classes does the Melbourne Building Act divide proposed buildings? Give particulars of each. What

steps would you take to insure compliance with the Act (a) in the case of a set of offices, (b) in the case of a public hall, and what differences of requirements and procedure is there likely to be in the cases?

6. In the case of a proposed hospital, what requirements in the Public Health Act must you comply with, and with what special information must you supply them?

Practical Geometry and Perspective.

1. Define a sector, chord, segment, arc of a circle.

2. Define a parallelogram, a trapezoid, trapezium. Give examples.

3. Show the method of drawing the following polygons on a given straight line, 1 inch long:—Pentagon, heptagon, octagon.

4. Show the method of dividing a straight line with any number of equal parts. Erect a perpendicular at the centre and at the end of a given line. Draw a circle which shall pass through the three points of a triangle. Describe a square which shall be equal to two given squares.

5. Construct a Gothic trefoil and cinquefoil in a circle 5 inches in diameter.

6. Draw an elliptical arch having a span of 6 feet and a height of 2 feet, and show joints in masonry; scale, 1 inch to 1 foot.

7. Draw a mitre section at an angle of 45 deg. of a cornice of which the sketch is a section at right angles to the wall.

8. Draw in isometric projection a cube having each edge 5 inches long, pierced at each side in the centre with a circular pin 2 inches in diameter, and projecting 4 inches beyond each face.

9. Show how to obtain in elevation the lines of the diagonal pointed ribs of an ordinary quadrilateral vault 10 feet square; scale, 1 inch to 1 foot.

10. Draw in perspective the arcade shown in plan, elevation and section on accompanying sketch, and fill in details of mouldings to arch and piers on one opening at each side of angle. Show the method of finding the projections of cornice at angle.

Note.—Question No. 10 must be attempted.

REFRESHMENT BARS.

PREVENTION OF BOILER EXPLOSIONS.

We have recently examined and adopted for use a very clever and effective arrangement for the prevention of kitchen boiler explosions, and we unhesitatingly recommend its adoption by architects and builders. The frequent reports in the daily papers of fatal kitchen boiler explosions makes the subject a very important one during the present severe frost. But as prevention is better than cure, we urge that such precautions should be taken as will render such accidents at all times impossible. Householders take their apparatus on trust, without having informed themselves how to act when hard and continued frost sets in. The "Climax" relief valve should be adopted for the prevention of explosions in kitchen and other boilers, a most reliable valve supplied by the "Climax" Relief Valve and Filter Company, of 6 and 7 Barbican, E.C. The hot-water apparatus usually fitted is in reality simple. A cistern filled from the main house cistern is placed, as a rule, somewhere in the bathroom, and from this cistern a pipe runs down to the wrought-iron boiler which is built into and forms the back of the grate in the kitchen range. The cold water flows down into the boiler by gravitation, and as soon as the fire is lighted the heated water, being lighter, passes up to the cistern by the return-pipe. Thus the flow and return system is safe so long as there is no stoppage of any sort in the pipes. But directly anything prevents the expansion of the water or the generation of steam, then a rumbling noise heralds the speedy approach of an explosion. Generally it is in the night, while the kitchen fire is out, that the water in the flow and return pipes gets frozen hard, with the result already indicated. The ordinary boiler fitted in most houses, when in place is not readily accessible except by removing part of the back-plate of

the range, and is without any provision for safety when free circulation is stopped. A boiler is fitted with a safety "Climax" valve placed at the extremity of a short length of piping (say 18 inches) screwed into the boiler, and the "blow-off" end is generally run into the chimney. At the warehouses of the Carron Company are several examples of these boilers, and when a safety-valve is ordered they supply what is known as the "Climax" relief valve,

which they have found to work with absolute certainty. There is nothing to get out of order, the valve itself is a piece of mica, and the whole is tested to, say, 50 lb. or 60 lb per square inch, and above that pressure it will blow off, affording the required relief to the boiler. These safety-valves can be fitted to any boiler for an extra cost of about 15s.; but to fit one to a boiler already in position would entail more labour, and the cost would be about 30s. During a hard frost, of course, the water may be prevented from freezing by banking up the fire at night with ashes and small coal, and so keep up a gentle circulation of water all night.

LIGHT AND AIR CASE.

AN application was made to Mr. Justice North *in re* Wasson & Fawell v. Pawson & Leafs, Limited, to obtain an injunction to restrain the defendants from erecting a building having frontages in Carter Lane and Dean's Court, which it was alleged would interfere with the light and air of a window and fanlight on the ground floor and a window on the first floor of plaintiff's premises, No. 4 St. Paul's Churchyard. It was contended that the obstruction was too far distant, being 80 feet to 90 feet away, the building rising 19 feet 3 inches in one part and 42 feet higher than the old buildings in another position.

The surveyors engaged for the defendants were Mr. E. A. Gruning, Mr. H. H. Collins, Mr. F. Chambers (of Messrs. Chambers & Son), Mr. Herbert Ford, Mr. Hudson (of Messrs. Hudson & Booth), and Mr. Robert Vigers. The surveyors for the plaintiffs were Professor Banister Fletcher and Mr. J. Douglas Matthews. The injunction was granted with costs in action.

SANITARY ASSURANCE ASSOCIATION.

THE fourteenth annual meeting of the Sanitary Assurance Association was held at the offices of the Association, 5 Argyll Place, W., on Monday last. Mr. Henry Rutherford, barrister-at-law, in the chair. Mr. Joseph Hadley, secretary, read the annual report, which stated that the work of the Association continued to be carried on in accordance with the plan initiated by it in 1881. County councils, schools and other authorities continued to seek the services of the Association, and to act on the advice given in the reports, plans and specifications of works furnished by its officers. The council stated that, while recognising to the full the excellent work done by the local authorities in carrying out the Public Health Acts, nevertheless, bearing in mind the deadly nature of sewer air, and our suffering still ensuing from unhealthy condition, they feel that such an organisation as the Sanitary Assurance Association continues to be indispensable.

The income for the year had been 4047, and after meeting all liabilities a balance was carried forward.

On the motion of the chairman, seconded by Dr. K. Macleod, and supported by Dr. Willoughby and Mr. Mark H. Judge, the report was unanimously adopted.

Mr. Roger Smith, professor of architecture at the University College, and Mr. Hy. Rutherford were re-elected members of the executive council.

Dr. K. Macleod was elected president of the Association for the year, and Sir Joseph Fayrer, F.R.S., Surgeon-General Cornish and Mr. Andrew Stirling were elected vice-presidents.

THE CONSTRUCTION OF AN AMERICAN BUILDING.

IN the *Engineering Magazine* for February, which is improving in every quarter, there is, among other important articles, one by Mr. Francis H. Kimball, who, with Mr. G. K. Thompson, designed and superintended the construction of the Manhattan Life Insurance Building—one of the loftiest of the new American class of structures, or sky-scrapers—descriptive of the mode employed in completing it within a brief time. Mr. Kimball writes:—

The temptation to excel some other record in the quick-building line, together with a desire for quick returns from rentals, losing but one season, is more than the investor can withstand. The architect has no choice in the matter; he must accept the inevitable, and bring to bear all his skill to accomplish the end desired in the best and most workmanlike manner.

It is not difficult, at the close of one of these quick-building operations, to trace the reasons which led to so successful a termination.

The most recent example in point of the actual time consumed in erection and in finishing the great bulk of the building—which has not been equalled up to the present time, pound for pound of iron and brick for brick of masonry—is the Manhattan Life Insurance Building, with which the writer is identified.

No comparison can be made between New York and Chicago records, as our building laws are much more rigid, in that they exact a greater degree of stability in the structural features.

In the case of the Manhattan Life Building, the time consumed in its erection may be divided into two parts, as follows:—Foundations ready for superstructure, five and two-thirds months; superstructure, eight months. The roof or eighteenth tier of beams was reached in exactly three months from the time when the foundations were ready, on which to set the first piece of steel composing the bolsters that support the cantilever system.

The time spent in preparing the foundations may seem to

those unfamiliar with this work scarcely consistent with the progress afterwards made, but the architects found that, in view of the unsatisfactory nature of the ground composed largely of quicksand, the usual methods employed, such as piling or masonry, were inadequate for the purpose of a foundation to sustain the great concentrated loads, and they thereupon decided to reach bed-rock, 57 feet below Broadway, by some unprecedented means. They finally concluded to introduce the pneumatic process used in sinking bridge piers to rock.

Sinking the piers to bed-rock rendered the building independent of any outside operations, either building foundations or tunnels. The fact that they were the pioneers in this undertaking, so far as the application of this principle to building work is concerned, led to much carefulness on the part of the engineers, Messrs. Sooy Smith & Co., in respect to the probable effect on the foundations of adjacent buildings, and that there might be no disturbance of such foundations, by reason of going so far below them, no attempt was made to force this work to the degree attained in bridge-work where operations are carried on in an open country.

The magnitude of the work may be better understood by reducing it to cubic yards of masonry. This substructure, which starts on bed-rock and continues up to the level of the cellar floor, consists of fifteen piers, varying in size from 9 feet in diameter to 21 feet 6 inches by 25 feet square. The caissons made of steel corresponded in size to the piers they sustain, and were 11 feet in height. These caissons were filled with concrete, and contained altogether 1,260 cubic yards. The number of bricks used in the piers amounted to 1,500,000.

From this it may be seen that a good-sized building was sunk out of sight before any part of the superstructure could be begun.

The fact that a new method, with more or less experimental work attending its adoption, had to be devised, and the really large mass of masonry forming the piers, are sufficient excuses for the length of time consumed in this feature of the building. It was a work which in olden times might have taken twelve months. Even the progress attained was due to the fact that three relays, or gangs, of men were employed in sinking the caissons, thus giving the work the benefit of the full twenty-four hours in one day for the entire period of five and two-thirds months, except in the case of the masons, who worked only during regular hours.

Suffice it to say that in three months about 5,800 tons of

steel were raised into position. This was not accomplished, however, without night work. When the foundation work was prolonged to September 1, the prospect of completing the building on May 1 was not promising. A council was held—attended by the building committee, architects and builders—the purpose of which was to incite the builders to greater activity and also to settle upon a plan for beginning and continuing night work until the roof was reached.

This meeting resulted in the institution of day and night gangs of men for the erection of the steel frame; and by reason of the time which, in consequence of the delay in the foundations, the contractors for this branch of the work obtained for the making of the wrought material and the delivering of the same within a short haul of the building, coupled with the fact that great care was taken at the rolling mills in laying out the various members to templates, so that when they were assembled at the building no fitting was required, the work of erection went on without interruption from the beginning to the end. Recalling the incidents of these three months' work, and the system employed to produce the quickest results, it seems that no mistakes were made and that every moment was counted.

To better illustrate the magnitude of the skeleton, I may say that there were girders weighing 40 tons, many columns of 10 and 12 tons each, and cantilevers of 80 tons (in four sections of 20 tons each), the length being 67 feet.

All of these heavy members required special means of transportation; the heaviest girder had to be rolled from the dock to the building by night, the task requiring three nights. It took just twenty minutes to raise it from the street to its position on the second floor.

On account of the great risks where material must be raised 300 feet in the air, and the haste with which the work must be done, the setters of iron and stone work should be picked men with certain qualities, the most prominent of which must be good judgment and steady nerves. It is rarely that serious accidents and even deaths are not recorded against buildings of even less magnitude than the Manhattan Life Building, but, strange to say, in this case there was no loss of life, and but few accidents worth mentioning. The work was greatly facilitated by the use of a travelling frame, with a derrick at each angle, by which material could be easily disposed of as it was raised from the street and placed in its proper position.

It was considered advisable to begin the brick masonry when four storeys of the steel frame had been set in position. This enabled the frame-setters to keep in advance of the other

trades. As far as possible this plan was pursued throughout, but inasmuch as bad weather has no effect on iron and steel, while with masonry the contrary is the case, at times it was necessary to lay off the masons while the others pursued their work. When high winds prevailed all work had to cease. But with good weather, when all could work advantageously, the masons could hardly hold their own.

There seemed to be a friendly rivalry between the two trades as to which should outstrip the other, and the greater the exertion the brighter was the prospect of closing in the building before cold weather set in.

Rough piping both for plumbing and steam began when the masons had reached the fourth storey, and continued without interruption until all the lines, vertical and horizontal, with all their branches, were in position. In the meantime the masons had begun setting the fireproof blocks forming the partitions, and as far as practicable this was carried along with the advancement of the outside walls.

When the partitions of a storey had been set, the electrician ran his wires, enclosed in conduits, to the various fixture outlets. One can hardly realise now that this "roughing," as it is called by the workmen, is concealed from view—that more than five and a half miles of gas, water, waste and vent-pipes, five miles of steam pipes and thirty-five miles of electric wires were required to perfect the respective systems. The facing of the front on Broadway contains about 30,000 cubic feet of stone, which was cut and set in position in eighty days.

It was not at first the idea to undertake to finish more than ten storeys by the first day of May, as the plastering could not be commenced until the winter was well advanced, and the outlook for enclosing the roof seemed distant and discouraging. When the twelfth storey was reached a temporary roof was deemed necessary for the protection from rain and snow of all the storeys below; and such roof was constructed, and was of great help in removing all fear of damage to the finer grades of interior fittings.

Immediately thereafter plastering was begun, temporary heat was supplied, windows enclosed, and a general advancement made towards the completion of the storeys below. There was no cessation, however, in building above this temporary roof. Fortunately the weather was propitious, causing but little delay. The building was permanently enclosed by the time severe weather set in. Then all the forces that could be brought to bear were employed in the supreme effort of getting the entire building in such condition that

tenants could occupy on the first of May any rooms that they might choose. It was successful. It proved a good investment for the company, as the greater proportion of the offices rented were above the sixth storey.

To follow all the different trades and describe the various methods employed to force the work almost beyond the limit of human endurance would be an interesting story. Suffice it to say that to the layman there can be no realisation of the vastness of the undertaking.

Take the laying-out of the engineer's department—the boiler and engine, the electric and elevator plants, the plumbing and heating systems contained in a building of this magnitude, the decorative treatment of the interior, employing the carpenter and cabinet-maker, plasterer, marble-worker and metal-worker (on stairs and elevator fronts), the mosaic and tile flooring, gas and electric fixtures for lighting, to say nothing of a more or less ornamental exterior—and it seems hardly less than a miracle that all these different interests, all large because the building is large, could have worked harmoniously together, and achieved such satisfactory results in the period of eight months.

It might be asked, have manufacturers of building material kept up with the rapid advance in methods of handling, producing articles that will set more quickly, and reducing to the minimum the danger of destruction, such as that from dampness proceeding from brick, plastering and concreting?

If the "drying-out" of a building could be reduced to a few weeks instead of months, the length of time required for its erection would not be so much a matter of uncertainty. Some thought has been given to the mixing and manufacture of plaster, the application of which is made more simple than formerly by certain quick-setting qualities which make it practicable to put on the wood trimming within a few days after a room is white-coated.

There is yet room for improvement in the direction of freeing the process of plastering from dampness, and rendering it less objectionable from the standpoint of cleanliness to those who must follow the plasterers. But there is one feature of the mason's work to which much attention has been paid during the past ten years, but seemingly not in the right direction; for the difficulty remains although the material is harder. I refer to fireproof blocking used for partitions and flat arches between beams. The blocks designed for partitions are not of uniform size; therefore the surface of one side of the partition becomes very irregular, as the mason lays up one side to a line.

J. ATTWOOD.

STOURBRIDGE.

The only Attwood in the Trade.

The plasterer must even up with plaster, the thickness of which varies anywhere from half an inch to 1½ inch. It cannot be expected that the shrinkage of plaster will be uniform, to say nothing of the danger of freezing when the work is done in the winter months. Fireproofing of floors between beams consists usually of flat arches formed of terra-cotta blocks made hollow to secure lightness. These blocks do not make up a thickness equal to the depth of the beam, where the beam is more than 8 inches. They vary in depth according to the span between beams; and where the beam is more than 8 inches there is a space above the arch to be filled, in order to meet the material of which the finished floor is composed. This space may be 4 inches, possibly 6 inches—sometimes more, sometimes less, according to the depth of beam. The concrete is generally composed of ashes and cement, especially when saving in weight is important.

Such a foundation is not of the substance required where there is a direct action thereon—as in the case of tile or mosaic floors—proceeding from the heavy and constant traffic usual in business buildings. Consequently such floors show the natural impact of the spongy concrete by numerous cracks, which, in the case of mosaic floors, can never be properly repaired.

This defect is not the only one of importance. A large percentage of the dampness usual in masonwork proceeds from this source. As this concreting is usually done just before the laying of the floors, it is quickly covered in, and dampness must pass through the wood-flooring in the process of drying-out. It is natural to suppose that kiln-dried lumber will absorb much of the dampness, and swell in consequence, so that afterward, when heat is turned on, it will shrink and open at every joint. More thought should be paid to a remedy for this, which may properly be termed a defect. Arches could be made that would reduce the space referred to, thus removing an element which, although it may not materially retard quick building, causes much of the criticism on the defective work (so considered) now credited to rapid methods of building. Other features no doubt enter into this class of building to which attention might be directed with profit to the builder, but it is hardly possible to discuss them in detail here. The individual experiences of others would be interesting and valuable.

Without co-operation on the part of the builder, the architect's suggestions are of no advantage, and the work lags in consequence. It is important, therefore, that none but the most reliable men should be selected to do the work. The

architect, moreover, should make the selection, for if he is to come in for his share of censure in case of delay, it is better that he and his own men should wholly deserve it than that he should suffer for mistakes over which he has had no control. Should the whole work pass into the control of one firm (usually masons), it should be an arrangement satisfactory to the architects.

The architects of the Manhattan Life Building, Messrs. Kimball & Thompson, were ably assisted throughout, and they take great pleasure in publicly acknowledging their indebtedness to the different firms who aided them to make so remarkable a record.

The secret of success always lies in constant, unremitting push in every department. Begin at the very beginning; an ounce of push at the start is worth a pound of push at the end. Start the trades whenever and wherever it is possible so to do, and keep up the tension; then satisfactory results cannot fail to follow.

THE PUBLICATION OF TENDERS.

IN *The Contract Reporter* of the 1st inst., among the tenders was one "For Works in Connection with Construction of New Weir, for the Banks of the Clyde Committee of the Town Council of Glasgow." The publication has been made the subject of a discussion at the last meeting of the Council, as will be seen from the following report in the *Glasgow Herald*:—

It was reported by the finance committee that at a meeting, held on the 25th ult., it was agreed to recommend that the offer of Messrs. Peter M'Kissock & Son, amounting to 21,795*l.* 4*s.* 6*d.*, for foundations and piers of the proposed weir should be accepted. At a meeting, held on the 1st inst., a letter was submitted from Messrs. Borland, King & Shaw, writers, stating that, for the reasons therein mentioned, Messrs. Peter M'Kissock & Son see no alternative but to withdraw their offer for the construction of the foundations and piers of the proposed weir or tidal dam across the Clyde at Glasgow Green. The committee, having had before them the treasurer's report on the five lowest tenders, resolved to recommend that the tender by Messrs. John Paterson & Son, Limited, should be accepted, being the second lowest of the tenders sent in. The amount is 26,104*l.* 0*s.* 6*d.* This price provides for the upper portions of the piers being constructed of freestone instead of granite.

Manufacturers of Wrought Metal Work, Architectural Carving and Joinery for Ecclesiastical Purposes, Domestic and Public Buildings, Lighting Appliances, &c.

Estimates given to Architects' own designs. Work can be inspected during execution.

SPECIAL ATTENTION GIVEN TO ARCHITECTS' DESIGNS

Treasurer Gray, in moving the adoption of the minutes, said with reference to the construction of the weir, the committee had presented to them seven offers. One amounted to 41,000*l.*, another to 32,000*l.*; the third, that of Messrs. Hugh Kennedy & Son, to 27,438*l.*; the fourth, Messrs. Charles Brand & Son, to 26,681*l.*; the fifth, Messrs. Morrison & Mason, to 26,569*l.*; the sixth, Messrs. John Paterson & Son, to 26,104*l.*; and the seventh, Messrs. M'Kissock & Son, to 21,795*l.* The committee considered that the last offer was abnormally low. The five lowest offerers were remitted to the measurer, and after one or two unimportant alterations had been made they were returned, and the committee agreed to accept the lowest. Since that time the offerers had found that they had fallen into error in making their offer. There was an unfortunate withdrawal of a quotation on which they relied in making their tender, and the next offer was much higher than the one withdrawn. He thought they might have insisted upon the offerers keeping by their offer, but it was, perhaps, as well that this matter should have been discovered in time, instead of at a later date. Something had been said about the figures appearing in the newspapers, but there was a growing feeling in favour of publicity, and that was carried to the greatest extent.

Preceptor Dickson said that he did not think the public were entitled to information as to what was done in committee; they were entitled to get it after the minutes had come to the Town Council. He thought that it was a great pity, especially in contracts of this kind—whoever was the party that revealed them—that they should be communicated to the community at large. They saw the result of it in the minutes. If these contracts had not been made public, in all likelihood the city would have saved 4,000*l.*

Mr. Macfarlane explained that it was after the committee had met and accepted the offer that the figures appeared in the papers, but not until then.

Mr. Martin pointed out that from Treasurer Gray's remarks it might be naturally inferred that it was through the influence of some member of the committee that the estimates for the bridge had got into some particular newspaper. It was not through any person on the bridge committee that the estimates got into the newspaper immediately after the meeting, but it was arranged by the bridge committee at their meeting that their chairman should give the figures to the reporters, who were at the door. The information was not given through any newspaper people having influence.

Mr. W. F. Anderson pointed out that eight or nine months

ago he called attention, on a matter of privilege, to the fact that proceedings in committee were grossly outraged, and now the citizens of Glasgow were compelled to pay 4,380*l.* additional because this information had gone from the committee through some one. The paragraph could not have been picked up in the Square; it must have been given. The estimates of the various contractors must have been supplied to the press. He protested against that matter. He did not care if there was an army of reporters, no matter should get into the public prints until it was first sent to the members. The result of the disclosure of the information in this case had been that the rate-payers had to pay 4,300*l.* extra, because the information was published before the deed was sanctioned by the Town Council and signed.

Baillie A. Murray regarded the question as one beyond the newspapers. At a meeting of the committee he had asked whether the lowest estimate of Messrs. M'Kissock had been accepted by the sub-committee. He was certainly given to understand that it had not, and that it came before them for the first time at the meeting on February 1. Now he found that the estimates were before the sub-committee on January 28. There were present four members. It was agreed to accept the lowest offer. He called attention to the practice of the committees of Town Council. He believed that the rule was—and probably it was right—that no communication should be made to the offerer that his offer was accepted by the sub-committee until the offer had been confirmed at a meeting of Town Council. He was not sure that this was a correct proceeding. It was quite true that an offer accepted by a sub-committee could not be held to have been legally accepted without this confirmation, but as between honourable parties contracting, he believed when an offer was accepted by a sub-committee and intimated on the spot to the offerer he would be bound by his offer. He might escape in a court of law, but he did not think that any honourable offerer would seek to do so on such grounds as those. It was worth the consideration of the Town Council whether an offerer should not receive immediate intimation of the acceptance of his offer. It could easily be seen how by the premature disclosure of information a door might be opened for arrangement between contractors. But while he said this, he was quite satisfied that nothing of the kind had occurred in this case.

Mr. Main wished the letter to be read which stated the points in which the offerer had made mistakes.

The Lord Provost said it did not affect the crux of the

question. The question was, How was the information given to the press, and the Corporation caused to suffer loss thereby?

Mr. Walter Paton thought the question was whether Messrs. M'Kissock were legally bound to do the work for the sum stated in their original offer. If they were legally bound, he wanted to know why the committee recommended the Council to accept a second offer which was not so favourable to them.

The Clerk (Mr. Monro) did not think it would be wise to say much on the subject at present. Of course the committee had recommended the proper course. He thought Messrs. M'Kissock were entitled to withdraw.

The Lord Provost said they had been advised that the Council not having accepted Messrs. M'Kissock's offer, they were entitled to withdraw.

In reply to a question, the Lord Provost stated that the error in the tender was in the first instance by a sub-contractor for the coffer dam, and in the second by Messrs. M'Kissock themselves for the granite.

Mr. Campbell subsequently said that in order to save the time of the Council it was desirable that the standing orders should be suspended, and that the motion of which he had given notice should be passed.

"That a committee be appointed to inquire into the circumstances under which the various tenders for the construction of the foundations and piers of the proposed tidal weir were communicated to the press before the same were submitted to the Council, and to report whereby a probable loss to the Corporation of over 4,000*l.* has been or may be caused."

Mr. Graham said that as one of the members of the sub-committee he did not object to the appointment of a committee, but he should like to see the scope of the inquiry extended, because there were many matters quite as important as these figures which appeared in the newspapers.

Bailie Alexander Murray said they should confine themselves to the matter immediately before them. If they wished to take up something else that would be done later on.

Mr. Battersby said he had made complaints as to the matter over and over again, and he had been told by gentlemen more deeply interested in giving information than he was, "You can use your own judgment." His conviction was, that if they were to limit the inquiry they were simply leaving scope for information on other subjects being given to the public. They should take up the matter fairly and squarely, and lay down a

distinct principle on which a resolution should be framed, to be acted upon by every member of the Council. As having some connection with the press he stated that he had never given a fragment of information to any newspaper.

Mr. Campbell said he had taken up a specific case, which involved the whole principle on which they could base some general resolution dealing with the whole subject.

The motion was adopted, and the following committee was appointed:—The Lord Provost, Bailies Alexander Murray, Chisholm and Dick; Messrs. Ure, Gray, Crawford, Macfarlane, W. F. Anderson, Graham and Campbell, Mr. Campbell convener.

LIGHT RAILWAYS.

THE following report of the committee of conference of local authorities has appeared:—

The committee have considered the subject referred to them, namely:—

1. How far the usual requirements of the Board of Trade as to constructing and working new railways may fairly be relaxed, especially in the case of lines built through sparsely-populated and agricultural districts.

2. Whether additional legal facilities for obtaining powers to construct tramroads and light railways are necessary or desirable.

They have given special attention to the case of light railways in agricultural districts, and they have also considered tramways and tramroads, as well in rural districts as in urban districts not of the first magnitude, but under this head they have not considered the circumstances of main lines of railway or tramway on which the traffic may be expected to be of great volume. For their guidance they obtained from the Board of Trade the Acts of Parliament and the existing regulations bearing upon the subject, and they consulted with its officers as to the practical effects both of the Acts of Parliament and the regulations upon railway construction and working. They were also furnished by the officers of the Board, by the Foreign Office, and by members of the committee with information upon the subject from abroad. In compliance with a request made to him Sir Joseph Crowe, K.C.M.G., C.B., has sent them an account of the law and practice in France under which land is acquired compulsorily for railways of local interest in that country. The committee consulted those

of their number who are acquainted with special divisions of the subject. The information given by Mr. Jackson as to the views of the existing railway companies was supplemented by valuable evidence from Sir Henry Oakley, the honorary secretary to the Railway Association. Upon the information thus acquired, the committee submit the following report:—They find that the existing law in Great Britain specially affecting the construction and working of light railways is mainly contained in the Acts of 1864 and 1868, and the law specially affecting tramways in the Act of 1870. In the case of tramways the law necessitates a confirming Act, even where no compulsory powers of taking land are demanded. Tramroads, as distinguished from tramways, are only dealt with in a Standing Order of the Houses of Parliament. Practically no light railways have been constructed under the general Acts of 1864 and 1868, owing, in part, it is alleged, to the consent of all landowners and other parties beneficially interested, and the absence of opposition from any railway or canal company, being necessary before the Act can be made use of. The mileage of such lines constructed under special Acts has also been inconsiderable. This lack of progress in rural districts has also been in great measure due to the want of latitude left to the Board of Trade by law, and in other cases by the conditions which the Board considered it their duty to impose for the public safety. It has also been stated that obstacles have arisen in the case of tramways and tramroads in consequence of the local authorities requiring conditions which were considered too onerous by the promoters of new schemes. The committee believe that the impediments to construction may be greatly diminished, and that on a large proportion of such lines as are contemplated by their inquiry the regulations which have been enforced with a view to public safety may be considerably relaxed. In the case of lines of small traffic, having few trains in the day and working at a moderate speed, there is little risk compared with that occurring on great trunk lines having numerous sidings and branches, and carrying, at high and varying speeds, a complicated traffic of passengers, merchandise, minerals and cattle, at all hours of the day and night. It seems reasonable that details as to route, width of gauge, fencing, level crossings, bridges, gates, the use of public roads, stations and station requirements, signals, continuous brakes, and many similar matters—unnecessary expenditure on which, taken together, adds greatly to the cost—should differ in different parts of the country, depending in each case upon the nature of the country and the

traffic to be conveyed. The same remarks apply to limitation of speed and regulations for insuring reasonable safety in working. There are several other items involving expenditure, such as the provision for deposit of security, the lodging of plans, advertisements, &c., in which there is room for considerable economy. The committee think that it is not reasonable that undertakings of limited scope, when they are approved of by the locality they are intended to serve, should be forced, as they are now, to have recourse to the expensive tribunal of a Parliamentary inquiry. The committee are of opinion that the recent creation of popular local authorities of various degrees throughout Great Britain opens the door to an escape from the great cost attending applications to Parliament, by enabling powers and responsibilities with reference to the authorisation and control of light lines to be conferred on those bodies, and that the time has arrived for Parliament to consider whether this should not be done, an ultimate appellate jurisdiction being reserved to the Government department charged with the inspection of railways, which, it may be assumed, would be exercised with due regard to the existence of such local control and responsibility. If this were done, the initial cost of construction and the expenses of working could be so greatly reduced that many light railways and tramways, promoted either by independent companies or by the existing lines of railway and tramway, could be undertaken to the great advantage of districts, and especially agricultural districts, at present without satisfactory means of transport. The committee suggest that proposals for the construction and working of such lines should be submitted in the first instance to the County Council (with exceptional provisions as to large municipalities), subject to precautions insuring that the interests of those directly affected are duly safeguarded. In all cases a majority of assents in number and value of owners and frontagers should be required, and in cases of compulsory acquisition of land there should be a power of appeal to the Board of Trade. If any doubt should arise as to whether a proposed line is a light railway, to be dealt with locally, or is a scheme which, on account of its magnitude or otherwise, should properly be dealt with by Parliament, the committee think that the Board of Trade should determine the question. The committee are doubtful whether it would be within the terms of the reference to them, and they refrain from giving an opinion as to whether and, if so, on what conditions, it is desirable that local authorities should be empowered to contribute funds towards, or otherwise take part in, undertakings of this character.

METROPOLITAN SEWAGE.

THE main drainage committee of the London County Council have reported the result of Mr. J. Parry Laws's and Dr. Andrewes's investigations into the bacteriology of sewage. These investigations showed that if the organisms existing in sewer air were derived from those existing in sewage the bacteria of sewer air should bear a close resemblance to the bacteria of sewage. On contrasting the prevailing organisms of sewage with those of sewer air they were found to bear no resemblance whatever to one another; indeed, so far as the investigators were aware, not a single colony of any of the organisms found to predominate in sewage had so far been isolated from sewer air. Attention was also specially directed to the possible occurrence of the typhoid fever bacillus and the diphtheria bacillus in ordinary London sewage. Therefore every colony which seemed likely to belong to either of these species was the subject of careful investigation. No evidence, however, of their occurrence in ordinary sewage was found. It was pointed out that the failure to find those organisms in ordinary sewage no doubt arose from the fact that the infected material constituted such a minute proportion of the total bulk of sewage discharged by the sewers. The mathematical chances, therefore, of detecting those organisms were exceedingly minute unless they were capable of vigorous growth and multiplication. Realising this fact, search was made for the typhoid bacillus in sewers where it might be expected to exist in much larger proportion. On examining sewage taken from the sewer draining the fever block at the Eastern Hospital, after disinfection had been discontinued for a short period, the existence of the typhoid bacillus was satisfactorily shown—an important fact which had not hitherto been demonstrated. A series of experiments were also made to determine the fate of the typhoid bacillus in sewage, in order to verify or disprove the statement made by many writers that disease germs, such as the typhoid bacillus, found in sewage a suitable soil for their growth and multiplication. On careful investigation it had been found that the bacillus of typhoid fever was not only incapable of any growth and multiplication in sewage, but that after the first twenty-four hours it slowly and surely died out, its ultimate death under natural conditions being a matter of a few days, or at most one or two weeks. If the organisms which existed in overwhelming numbers in sewage did not exist in sewer air, how indefinitely remote was the possibility of the existence of the typhoid fever bacillus in the air of the

sewers? Sewage was, without doubt, a common medium for the dissemination of typhoid fever; sewage-polluted soil might give up germs to the subsoil air; but from the results of these investigations it appeared in the highest degree unlikely that the air of the sewers should play any part in the conveyance of typhoid fever.

RECENT BUILDING IN MANCHESTER.

A VERY great street improvement is the widening of the approach to Oxford Road Station, but to perfect what has been so well begun there is needed, says the *Manchester Guardian*, a skilful and judicious treatment of any new buildings that may be erected on the west side of Oxford Street and adjacent to this approach. The site and circumstances invite a new façade with a handsome entrance and staircase to Oxford Road Station. There is ample space for this, but the designer should be careful to see that any such additions are harmoniously welded into the existing structure. Additions manifestly stuck on, such as the stone doorways to the Rylands warehouse in Oxford Street, a little further to the south, or the King Street doorway work to the Consolidated Bank, are lamentable. Probably the best treatment that we have in Manchester of a comparatively small building occupying a rather difficult corner site is the office of the Scottish Widows, at the south-east corner of Albert Square. Any town or any architect might be proud of it. At the south corner of Whitworth and Oxford Streets is a new and notable building. This is an instance in which twilight improves the effect. Some of the details carry us away for a moment to the Palace of Heidelberg, yet we ask ourselves why should this great pile look so mean and wanting in true dignity, in spite of its height and massiveness? The answer comes readily, because it is more or less of a sham. The mouldings and the ornament are all designed for a stone treatment. It is a stone idea. To cast such features in a mould is a misuse of terra-cotta and a degradation of architecture to what may be called "the wedding-cake style." Terra-cotta makes an excellent servant but a bad mistress. Guided and governed, and above all kept in its place, it is a most useful and effective building material. The last painful additions to the building are two ugly granite tablets, recording the names of the streets, in very common-looking letters, made even vulgar by gilding. Crossing over to the Stockport Road, we come (nearly opposite Devonshire Street) to a brick and

A large number already in present use giving full satisfaction. Unrivalled.

COMBINED STAYS AND FASTENERS FOR CASEMENTS

AND
FANLIGHTS

We beg to call your special attention to our Patent Combined Stay and Fastener, which, from its great advantages and easy mode of use, can well claim a superiority over the common kinds. You will notice that this Fastener has no complex system of working, is easy to fix, and, whether the casement is open or shut, does not project into the room, but hangs down the centre of the sash free from curtain or blind. The advantage of this Patent Fastener is that, being fixed in the centre of the sash, it affords protection against sudden gusts of wind when open, and keeps the sash safely closed when shut, as it acts as a fastener for the casement as well as a stay. Each of the three kinds of Fasteners affords the same advantages in all respects, as, though varying in shape, size, and price, are only different ideas of the same method. These Casement Fasteners can be used both for wood or iron, for single or double casements. The special pattern is used for fanlights to open outwards, and all can be used both for right or left hand. We can supply these Fasteners in any number of links, according to the extent the casement is required to be opened. We may also note that the Fasteners are well made and finished, can be had both in brass and iron, and are, therefore, well suited for any kind of residence. Quotations and further information will be given on application. Also testimonials. Please state in ordering whether you require them for single or for double casements.

Stay and Fastener shown in Action.

Office: 175 Strand, London, W.C.

terra-cotta chapel, fresh and vigorous in its design, and where, with comparatively slight exception, terra-cotta has been duly kept in its place. The whole work suggests economy, but there is nothing mean about it. It possesses the dignity of simplicity, directness of purpose and appropriateness. There is a new block of shops and offices at the south-west corner of Deansgate and West King Street which deserves a word of commendation. The outline and general treatment and the plainness of detail are, for the most part, good. It is unfortunate that the great mass of the chief corner, and far down both streets, seems to be standing on nothing. The supports to which the building owes its very existence are ungenerously kept out of sight and out of mind. Much better contrived are the Imperial Buildings in Cross Street, where the great weight above has adequate support below, without any undue darkening of the shops. It is a great pity, too, that the name and business of the firm which is emblazoned in two broad bands upon the body of the angle turret is not so treated as to be a decoration rather than an eyesore, and so as to be a proper part of the design of the building, instead of appearing as an afterthought, put on, as most shop names and titles are, almost anyhow. Seen from the corner of St. Ann Street or Deansgate, the big skylight stares one in the face unpleasantly. It attracts attention, and when we look we see only what is unsightly. The position is too conspicuous to be thus neglected. We feel regret that a good conception, as this block undoubtedly is, should be so marred by want of painstaking in detail. The Dugdale Chambers block of building in St. Mary's Gate arrests attention, if only by the newness of its stone. The windows seem sensibly treated for light and convenience, without making the front so painfully weak as to excite wonder that it still stands. There is a plainness of detail which is well suited to such a building, such a street and such a city. The general conception of the design, too, is good; but the detail of the centre gable, a good feature in itself, is unrefined and inartistic. The chimneys are not high enough nearly, either for good draught to the flues of the upper rooms or for appearance's sake. Moreover, the design of these chimneys probably looks much better in the drawing than in execution. The main gable and the chimneys especially should have been studied on the spot before being put into work. We should have preferred a little more evident support below to the superstructure, but there is more than is sometimes given in such cases. The worst minor feature is the detail of the fanlight of the street entrance to the chambers. This little bit of detail, which is very much in

evidence, is poor and mean. Generally there is evidence of care and judgment about this façade. It is a pity that all details should not have been well and thoughtfully worked out. The building is not very well joined on to its neighbours. Unsparring pains and trouble and experiments on paper and by model are the only ways to secure graceful fitting in of one building to another. Altogether, we are disposed to welcome this addition to our street architecture, but we regret that a little more care and thought and taste were not bestowed upon some of the details.

PATENTS.

[This List of Patents is compiled specially for this Journal by Mr. G. H. Rayner, of the firm of Rayner & Co., Consulting Patent Agents, 37 Chancery Lane, London, W.C., from whom all particulars and information relating to Patents may be had gratuitously.]

APPLICATIONS FOR PATENTS.

- 1943. Frederick Rayner, for "An improved casement window-holder or stay."
- 1960. Charles Major, for "Improvements in and connected with fireproof and ventilating floors."
- 1968. Robert Perrot Reid, for "An improved silent door-hook."
- 1995. William Edward Aldous and Frederick Digby Aldous, for "Improvements in ventilators for houses, factories, &c."
- 2049. Frank Beall King, for "Improved door-silencer."
- 2052. Harry Brierley, for "Improvements in sanitary cisterns."
- 2082. Edward Frederick Robertson, for "Improvements applicable to windows."
- 2172. Hugh Donald Fitzpatrick, for "Improvements in locks and latches."
- 2244. William Wall, for "Improvements in sewer ventilators."
- 2268. Samuel Bastow, for "Improvements in windows."

TO INVENTORS.—Patents for Inventions, Trade-marks and Designs secured; every assistance given to inventors. Specialists in Building matters. Information free.—Messrs. RAYNER & Co., Patent Agents, 37 Chancery Lane, London, W.C.

NEW READING CASE.

To Librarians of the Public Libraries and Reading-rooms.—A new handsome Reading Case can be supplied at a nominal charge of 2s., by post 2s. 6d., on early application to the Publisher, 175 Strand, W.C.

SPECIAL NOTICE TO THE TRADE AND OTHERS.

[Extract from a lecture on Architects' Libraries by Professor T. Roger Smith, F.R.I.B.A., at University College, October 10, 1893.]

"Lastly, let me recommend the back volumes of the professional journals. In the course of years all sorts of architectural topics come up in the public press and before the professional societies, and if you hunt through the indexes of these publications when you are seeking for information which eludes you in books, you will often be rewarded."

There has been a considerable demand for the back numbers of *The Architect* during the last three or four months, which we have no doubt has arisen from the remarks made by Professor Roger Smith, as contained in the above quotation; but the consequence has been that our stock of back numbers is getting very low, and consequently, in future, the charge for back numbers of previous date to January 12, 1894, will be 6d. each.

A few of the back volumes may still be had, price 12s. each.

EDITORIAL NOTICES.

The authors of signed articles and papers read in public must necessarily be held responsible for their contents.

No communication can be inserted unless authenticated by the name and address of the writer—not in every case for publication, but as a guarantee of good faith.

Correspondents are requested as much as possible to make their communications brief. The space we can devote to Correspondence will not usually permit our inserting lengthy communications.

VARIETIES.

At a meeting of the Harwich School Board, Mr. J. W. Start, F.S.I., architect, of Colchester, Clacton-on-Sea, and Harwich, was instructed to prepare plans of schools for 450 children on the main road, and for 350 children on the Bathside, both to be built on the ground floor, with covered playgrounds, lavatories, &c., in the basement. The sites for these schools have very bad bottoms, and will therefore necessitate piling and planking. The clerk was also instructed to advertise for tenders for the Lower Dovercourt Schools, according to plans prepared by the same architect.

THE Town Council of Heywood propose to build a hospital for infectious diseases, and power has been given to the Council to borrow 3,300*l.* for the hospital; 6,500*l.* to defray the cost of road-making, construction of boundary wall, &c.; and 550*l.* to pay for the furniture, fittings, &c. A further application to borrow 500*l.* for the cost of land is refused, because the Board understands that the site is already owned by the Corporation, being purchased for sewage disposal purposes and paid for out of a previous loan.

A MEETING of John Oakey & Sons, Limited, will be held at Cannon Street Hotel, E.C., at twelve o'clock on Wednesday, February 27, to receive the report of the directors and to declare a dividend. Mr. C. G. Oakey, nephew of Mr. Herbert Oakey, the chairman, has been elected to a seat on the board, with the position of deputy managing director.

THE Yorkshire branch of the Society of Medical Officers of Health, meeting at Keighley, discussed the question of the poisoning of water by lead. A resolution was adopted declaring that in the case of moorland water supplies either lead pipes should not be used or means should be taken to prevent the water acting upon the lead.

NOTHING having been done to repair the damage to the Kilkeel pier during the storm last December, the remainder of that structure has just been washed away during a strong south-easterly gale.

At the meeting of the North Berwick Dean of Guild Court, once more the application of Mr. John Macintyre, chemist, for alterations on his property was under consideration, and finally disposed of. The case has been hanging over for a considerable time. The Dean (Provost Whitecross) presided, and Mr. J. B. Lawson (of Messrs. Simpson & Lawson, W.S., Edinburgh) appeared for the petitioner. When originally before the Dean

of Guild Court some time ago, the application was refused, and Mr. Macintyre took the case to the Court of Session. Thereupon it was sent back to be dealt with by the North Berwick Court, on the ground that no reason for the refusal had been given. Subsequently, at a sitting of the Dean of Guild Court, which was not then fully represented, the case was continued for a fortnight. The North Berwick Court had the petition again before it a fortnight since, and it was further continued until the next fortnightly sitting of the court, on the ground that the plan as submitted was not in conformity with the requirements of the Police Act of 1892, and so as to allow of an amended plan being submitted by the petitioner. An additional plan was accordingly submitted at the Dean of Guild Court, and Mr. Lawson was heard in favour of the petition. After some discussion warrant was granted as craved.

THE North Berwick Police Commissioners held a meeting in the Council Chambers—Provost Whitecross presiding—to give opportunity to all persons interested in the drainage scheme adopted by the Board to be heard thereupon. No objectors appeared. The scheme, which is an extensive one, is to be carried out in accordance with plans prepared by Messrs. Belfrage & Carfrae, C.E., Edinburgh, at an estimated cost of 1,300*l.*

A FIRE occurred at Winterborne, near Dorchester, which resulted in the complete destruction of the famous old coaching hotel known as the Coach and Horses, damage to the extent of over 2,000*l.* being done. The conflagration is supposed to have been caused by a defect in a flue. The property was owned by Mr. R. H. Simonds, barrister, and is fully insured.

At an adjourned meeting of the Manchester City Council Mr. Alderman Hoy, chairman of the technical instruction committee, moved a resolution authorising application to be made to the Local Government Board for power to borrow 50,000*l.* (in addition to the 100,000*l.* already sanctioned) for the purpose of the new technical schools, and that, subject to such sanction, the tender of Messrs. R. Neill & Sons for the building of the schools at a cost of 141,545*l.* be accepted. The resolution was adopted.

ON Saturday next, the 23rd inst., Messrs. Wm. Densham & Sons, builders and decorators, of St. John's Wood, will give a dinner and social evening to some 120 of their employes, to celebrate the jubilee of their establishment in the building trades.

NATIONAL TELEPHONE No. 6.

Telegrams, "IRON, WELLINGBORO."

A SHOE-FACTORY fire broke out on the premises of Messrs. H. Garner & Son, Lower Willow Street, Leicester. The factory is of three storeys, with an extra range of attics lighted by skylights. A little delay occurred at one of the hydrants owing to the frost, and some difficulty was experienced in obtaining access to some parts, but the fire brigade succeeded in preventing the entire premises from being gutted. Owing, however, to the fact that every part of the building was heavily stocked, the aggregate loss was considerable, but is covered by insurance. The fire seems to have originated in the basement, and has thrown about 150 hands idle.

SIR W. D. PEARSON, the contractor, was on Tuesday elected member for Colchester. The Blackwall Tunnel is being carried out by his firm.

THE Edinburgh Town Council have approved of the arrangements proposed by the North British Railway Company for dealing with the traffic during the reconstruction of the Waverley Bridge.

THE first annual general meeting of Rowton Houses, Limited, will be held at 16 Great George Street, Westminster, at twelve o'clock on Wednesday, the 27th inst., to receive the directors' report and statement of accounts, to declare a dividend, to elect auditors and to transact the business of an ordinary general meeting.

ORGANISATION OF BUILDERS IN SCOTLAND.

FOR some time past the question of strengthening their organisation has been under the consideration of several of the leading Master Tradesmen Associations in the larger cities and towns in the country. The movement had its origin with the Edinburgh Master Builders' Association, who proposed that the various employers' organisations throughout the country should be affiliated much after the manner of the existing operatives' societies. With the object of bringing the proposal under the notice of employers in Dundee a deputation consisting of the president, vice-president and another member of the Edinburgh Association visited the city the other day and met the members of the Dundee Builders' Association, which is composed of masons, joiners and plumbers. They fully explained their proposals, and afterwards, says the *Dundee Advertiser*, an interchange of opinion took place. It was then decided that a special meeting of the Dundee Association should be held to consider the matter. This meeting was held in Mathers's Hotel. There was a large attendance, and Mr. Thomas C. Stocks,

the president, occupied the chair. General sympathy was expressed with the proposal of the Edinburgh Association, and the meeting decided to give it their warm support. In accordance with this resolution, the following deputation was appointed to attend a meeting of representatives of Master Associations to be held in Glasgow shortly, when steps are to be taken to form an organisation on the lines indicated:—Messrs. T. C. Stocks, J. B. Hay, Thomas Macaulay, William Bennett, D. P. How and Thomas Craig. Mr. W. Farquharson was also elected to attend the meeting as representing the master plumbers, and it was further agreed to ask the master plasterers to send a delegate. The proposal to have a forty-eight hours week, which is at present agitating trade circles in the Metropolis, was also under consideration. It was decided unanimously to resist the movement, the Association being of opinion that it was in the interests of the public, as well as of those more directly concerned, that the fifty-one hours week should be maintained.

THE RISKS OF HANDY MEN.

ON the 16th inst., Maidwell Hall, Northamptonshire, the residence of Mr. Reginald B. Loder, was totally destroyed by fire. An estate workman was employed in nailing felt to the inside of the roof to keep out the cold and draughts. The man accidentally knocked over the candle with which he was working, the felt became ignited and in a few minutes the flames had spread along the roof to half the house. The man seriously burnt his hands in trying to put out the fire. All the water hydrants with which the house was plentifully supplied were frozen. An ineffectual attempt was made to stay the flames with buckets of water, but in half an hour it was evident the place was doomed. Scores of villagers assisted in removing the furniture, all of which was placed on the snow-covered lawn, and was afterwards removed to the church and other buildings in the vicinity. The fire-engines from Market Harborough and Northampton were telegraphed for, but when they arrived the house was doomed. Only three small rooms at the north-east corner of the building were saved from the flames. The house was built in 1637, and was restored by the late Sir Robert Loder in 1885. It was a three-storey building and measured 150 feet by 120 feet. It was rich in oak paneling and carvings, all of which were destroyed. The furniture is damaged only by removal. The loss is between 15,000*l.* and 20,000*l.*, and is covered by insurance.

HEWETSONS, Tottenham LONDON, W.

Court Road, HOUSE FURNISHERS & DECORATORS,

Extract from THE GENTLEWOMAN (Mrs. PANTON).—"You can find all the furniture at Hewetsons', or if you are dubious of your own powers, you could either send me the pretty catalogue to mark, or my daughter could choose them next time she is in town, if you liked. The catalogue should certainly be seen; it is entirely a work of art, and most useful to country residents."

TRADE NOTES.

In a few days Messrs. Richard Johnson, Clapham & Morris, Limited, will issue to their customers a new catalogue, consisting of about 450 pages, with illustrations of most of the articles they manufacture and sell, such as patent fireproof wire lathing, nails, screws, general wirework, galvanised iron and zinc for roofing, wire fencing, hurdles, wire netting, gas-fittings, general ironmongery, lamps, stamped goods, &c. It will contain, further, six photographs, views in the works and showrooms, as well as colour lists of Messrs. Aspinall's enamel, and many pages of coloured illustrations of bedsteads. This catalogue has been prepared with great labour and care. About seven tons of paper specially manufactured have been used in it. The printing and type are all of the highest quality. The catalogue has a very carefully-compiled index, and contains many pages of useful trade memoranda as to the weights per square foot of metals, the length of different gauges of wire, &c.

AN improved system for the construction of skylights is being introduced by the Paradigm Construction Company, of Great College Street, Westminster, which will prove very valuable for ordinary skylights, greenhouses, &c.

OUR attention has been called by Messrs. Ellis & Co., 23 Strand Street, Liverpool, to the very superior quality of Ellis's asphalt roofing felt. It is 32 inches wide, and made in three qualities, the rolls being 25, 30 and 40 yards respectively. The felt is uniformly even and pliable—does not adhere, tear, or crack in unrolling—is sold by the lineal yard. Felt, being cheap and easy of application, and requiring but light timbers compared with a roof of slates or tiles, makes the most economical roofing yet known. It is admirably adapted for covering corn and hay-ricks, and sheds and stores, for agricultural, manufacturing, or other purposes, workmen's huts,

stables, &c. It is well adapted for the Colonies or foreign countries, dock and quay sheds, &c. Is extensively used in the construction of military camps, storehouses and drill sheds for roofing purposes; it is also useful for resisting the ground damp underneath bedding, stores, &c. Under slates, tiles and metallic roofs, being non-conducting, it is good for keeping buildings cool in summer and warm in winter, and so used for churches, houses, factories, exhibition and other public buildings, makes a more secure roof, repelling the heat and keeping out the wind and dirt; it also serves to deaden sound. Dry hair felt is also used as non-conducting.

THE new schools, Leighton Buzzard, are being warmed and ventilated throughout by means of Shorland's patent Manchester grates, patent exhaust roof ventilators and inlet tubes, the same being supplied by Messrs. E. H. Shorland & Brother, of Manchester.

NOTES ON NOVELTIES.

Maurice's Porcelaine.—This, it is claimed, for walls and woodwork is the best article in the market when a bright and durable finish is required; it is easy to work, and gives a lasting glaze equal to china. For ceilings the white is incomparable, and will keep its colour for years; it has binding qualities that prevent ceilings from cracking. For iron or metalwork of all descriptions it is a protective against corrosion and gives a beautiful finish, and on account of its heat-resisting qualities is in every way suitable for stoves, engines, electrical apparatus, &c. It is suitable for sanitary work, being in itself a sanitary invention giving an impermeable ceramic surface which will resist even hot water. For corridors, baths, w.c.s, lavatories, &c., it is invaluable, being washable and damp-proof. It is supplied ready for use in drums or barrels, and is applied the same as ordinary paint without priming of any kind. Two hundred tints are stocked, or any other colour or tint can be supplied within two hours' notice, or the ivory and white can be tinted with ordinary oil-tinters to any desired shade. Porcelaine is supplied to dry flat when required. Lanfranc Street, Lambeth, S.E., is the address of the Porcelaine Co.

THE quantities are being taken out for the new General Post Office in Dundee, of which Mr. Robertson, of the Edinburgh Office of Works, is architect.

LIBELLING CONTRACTORS.

THE following apology has been published by Mr. Sidney Webb:—"Will you allow me in your columns to express my regret for an unintentional error into which I have fallen? In a recent article in the *Contemporary Review*, on 'The Work of the London County Council,' I referred to the case of the York Road sewer, in which the lowest contractor's tender had been 11,588 $\frac{1}{2}$ %, whereas the main drainage committee executed the work itself for 4,477 $\frac{1}{2}$ % less. I added that it was clear 'that an agreement had been come to by the contractors not to compete with one another for this job.' I have now received from the solicitors of the tendering contractor an explicit denial that he was a party to any such agreement. I had no intention of saying that he was, as I was thinking rather of the contractors who did not tender on that occasion. But the words I used might give the impression that I thought he was a party to the agreement, and I hasten to say that I fully accept his denial, and that I regret that my sentence was not clearer. I have no wish to cast any doubt upon the *bona fide* character of the two tenders sent in, one of which was for 11,588 $\frac{1}{2}$ % and the other for 11,608 $\frac{1}{2}$ %. As a London ratepayer I am, however, all the more glad to think that the Council had the means of doing the work itself, with the result of saving 4,477 $\frac{1}{2}$ %."

HEATING OF CHURCHES.

In a letter to the *Evening Despatch*, of Edinburgh, the Rev. F. L. M. Anderson, of the Rectory, North Berwick, writes:—

I observe Mr. Mackenzie's letter in your paper of this evening's date, in which he says he still sticks to what he wrote in his first letter, and that he knows Grundy's system. In his first letter Mr. Mackenzie said that the hot-air system was as dangerous as the hot water. Now I am pretty sure Mr. Mackenzie cannot have seen Grundy's system working—though he may know it—for if he had seen it he would have at once seen that there cannot be the slightest possibility of explosion, over-heating, or conflagration. In the three unfortunate accidents quoted in your paper of conflagrations—(1) In an Established church at Greenock; (2) in a Free church at Helensburgh; (3) in a U.P. church, I forget where, but where damage was done to the amount of 500 $\frac{1}{2}$ %, and the building (iron) was destroyed—I am nearly sure all these were

caused by over-heated or frozen water-pipes, and I am positive too that, even if the greatest possible care be observed, these explosions cannot be assuredly guarded against, especially in such cold weather as we have been having, and that hot air is much safer than hot water. Mr. Mackenzie is a partner of Mr. Moncur's—a firm which deals in hot-water apparatus—and of course he must stick up for his and his partner's method. It will, however, be very difficult to shake my faith in "hot-air" apparatus, especially Grundy's system, or in the great many advantages they have over hot water; and Mr. Russell, the beadle of Dunfermline Cathedral, confirms my opinion. I and my friends are perfectly satisfied with Grundy's system, and I will have much pleasure in showing its advantages to any one who comes to see it on any Saturday at three o'clock. I am sure it will stand any test. Mr. Grundy writes me saying that he has never had a fire with any of his apparatus, and hopes he never will, as he is sure none could ever occur.

A great many clergymen of all denominations would agree with Mr. Anderson as to the advantages of the Grundy system.

CIVIL AND MECHANICAL ENGINEERS.

At the Civil and Mechanical Engineers' Society Mr. E. H. G. Brewster read a paper on "Water-waste Preventer Cisterns." He first drew the attention of the meeting to the necessity for these, and illustrated this by giving particulars of the quantity of water that would run to waste through small holes, e.g. a hole only one-sixteenth of an inch in diameter in a pipe having a pressure of not more than 45 lbs. per square inch would result in a loss of 648 gallons in a day. Attention was then drawn to the waste preventer cisterns of J. Ashley and T. Binns, patented in 1792 and 1793, or more than a hundred years ago. Waste preventer taps were incidentally touched upon. The modern types of water-waste preventer cisterns were divided into four classes. 1. Tip-up apparatus. 2. Cisterns with inlet and outlet valves only. 3. Cisterns divided into compartments and having more than two valves. 4. Cisterns worked in conjunction with syphons. The latter class was stated to be the one most commonly used at the present time. The "Tower" cistern was particularly alluded to as being one of the simplest and the foremost of the valveless type now very general. The "Paisley" was also described, as were many others. A vote of thanks closed the meeting after a very interesting discussion.

SANITARY SCIENCE AND FROST.

THE following letter from Dr. Rowand Anderson has just been published:—The present severe and long-continued frost and the discomfort and suffering thereby entailed, especially in the densely-populated districts of our cities, demonstrate this very serious fact, that all our sanitary science is unequal to protecting us from the wretched inconveniences, possible serious sickness and certain destruction to property arising from a severe frost. It is no answer that such a frost as we are now having is of exceptionally long duration. The present aggravated state of matters exists in a greater or less degree whenever frosty weather sets in. Not only, it appears to me, has sanitary science failed to prevent such a state of matters as now exists, but it has ignored and aggravated the sources of danger; and what are called sanitary appliances become nuisances in such weather as we are now experiencing.

The whole system of house sanitation, as developed chiefly by sanitary protection societies, falls far short of what the word protection should imply. It has added greatly to the responsibility of house proprietors, to the complication and cost of plumber-work, and to the disfigurement of our buildings; but in the presence of such weather as we are now having it is helpless, and affords no sanitary protection.

Some of the weakest points in the present system are:—

1. The insistence by sanitary experts that all pipes shall be placed where we see that the frost can so easily attack them.

2. The arrangements for the distribution of hot and cold water throughout our houses requiring pipes to be led in such directions that any accident necessarily leads to serious destruction to property.

3. The want of some simple method of protecting the water supply and service applicable to all classes of houses and tenements. At present the only one resorted to is to waste water at the very time when the supply is restricted.

4. The want of some seemly method of ventilating the soil-pipes and drains without disfiguring the outside of our houses.

I do not wish it to be supposed that I consider sanitary experts alone responsible for the failure of our present system. Architects must bear their share, and so must also the public. The latter, unfortunately, too often understand architecture to mean a mere matter of ornamentation, and not an art that primarily is one of pure utility, and of designing structures thoroughly adapted to the purposes which call them into existence. This must be based on the experience of the past

and the science of the present day, so as to ameliorate all the conditions of life and add to the amenities and comfort of all classes.

When the thaw sets in the destruction and discomfort will be serious; but if the attention of the public is thereby aroused to the necessity for finding a remedy for proved defects much good may be done.

THE ART OF BOOK ILLUSTRATION.

AT Toynbee Hall on Saturday last Mr. Joseph Pennell read a paper on "The Art of Book Illustration," which was illustrated by a number of views. The craving for pictures, said the lecturer, was as old as the world. The cave men who scratched a few lines on an arrow-head or the walls of their caves were the first illustrators. From them to the hieroglyphics of the Egyptians was, after all, but a step. Still, these drawings could not be reproduced, and the earliest examples of illustration in the modern sense of the word were the old block books. The earliest known of these was the picture of St. Christopher. A reproduction of a recent illustration by Sir E. Burne-Jones was placed before the audience, to show the advance in methods which had been made since then. Albert Dürer's work was the perfection of drawing, and Holbein, the first of our caricaturists, was a worthy compeer to him. Rembrandt carried on these traditions worthily, but with Vandyke and Rubens decadence set in. But modern illustration really owed its origin to a great Englishman, Thomas Bewick, who revived the traditions of the greater masters, and even rivalled the greatest of all book illustrators, the Japanese. William Hardy, Thomas Scott and Blake were among the greatest of his successors. About 1830 the French romantic painters followed in their footsteps, but there was one thing of which our nation should be proud, that, although these exquisite drawings were made in France, the wood-cutting itself was done in England by English men and women. The German, the Spanish school, of which Vierge was a brilliant example, and the American, with Vierge and Whistler, the latter in his opinion equal to Rembrandt, had carried the art of illustration to the grand position it now held. It was the one living and fruitful form of art. Oil-painting and Academy pictures might bring fame, but the illustrator of to-day was doing the same work as the great artists of three centuries ago.

THE EDINBURGH NORTH BRITISH RAILWAY HOTEL.

THE directors of the North British Railway have adopted the designs of Mr. W. Hamilton Beattie for the new hotel and general railway offices which the Company are to erect in Princes Street, Edinburgh, on the site between the North Bridge and the Waverley Market. Mr. Beattie's designs were chosen out of some half-dozen competitive plans submitted to the directors. They show a building which is estimated to cost 221,000*l.*, and which promises to prove one of the greatest architectural ornaments of the city, finely adapted to its surroundings, and combining stateliness and dignity of composition with great elaboration of detail.

In designing a building to please the public eye, says the *Scotsman*, Mr. Beattie had a good deal in his favour in a site as prominent as any in the city, unobstructed by any surrounding buildings and practically four-square, and in the result the building is imposing from any point of view. The style is described as a free treatment of Renaissance, which has given the architect ample scope in the picturesque grouping of windows, gables, turrets and chimneys. The main elevation is in Princes Street. Here we have a frontage of nearly 200 feet, rising six storeys from the street level to a height of over 100 feet at the crown of the roof. This elevation has several distinguishing features. One of these, which gives dignity to the entire building, is the great tower occupying the centre of the façade and rising to a height of 160 feet above the street. The other salient features are the single pavilions which, ending in cupolas at the roof level, flank the tower at each corner of the building, and with the tower have an important function in giving both unity and variety to the design. These are treated with prominent oriels on the lower storeys. The angle pavilions, separated from the main elevation by light-shafted pilasters, are crowned with turrets surrounding the cupolas. The lines of the tower are skilfully carried up beyond the roof by corner pilasters, ending in turrets, and a central turret springing from the midst of these, and ornately finished, crowns the whole. The massiveness of the tower above the roof-level is further relieved by ornamental clock faces. The general treatment of the main elevation is fairly bold on the lower storeys. The first and second storeys have arched windows handsomely grouped in fours on each side of the central tower, mullioned and transomed. In the next two storeys the

windows are square-headed. Above that the treatment is lighter and more ornate. The fifth storey windows are circular. This brings the design to the parapet, and the sixth storey is treated with dormer windows, which have several elegant features. The circular and dormer windows, the tower and the turreted cupolas, and the chimneys well grouped on each side of the tower, all combine to give to the skyline a picturesqueness which is very effective.

The elevation on the other sides is very much in keeping with what has been described. The angle pavilions with their finely designed oriels and turreted cupolas are the same as in the front elevation. To balance these a feature has been made of the gable which projects in the centre of the elevation to correspond with the central tower of the main front. The gable end has been treated with much art, and its windows are designed with greater elaboration to correspond with those of the central tower, and to harmonise with those of the angle pavilions.

While the site offered every advantage with respect to exterior treatment, the nature of the ground presented a good many difficulties in the way of internal arrangements. There is a great fall from the Princes Street level to the railway level of the North British Station, and to accommodate his building to this slope the architect had to make four storeys below the level of Princes Street. These will be dealt with later on. To take first the main floors, it may be repeated that the building being four-square has a central court about 70 feet square, which has simplified the problems of lighting, access and ventilation. The principal public rooms of the hotel occupy the west and north fronts on the level of Princes Street. Public restaurants and bars occupy the north-east corner. The North Bridge front at the ground level is to be chiefly taken up with shops, and the south front is to be occupied by the railway offices. The topmost storeys of the entire block, of course, will form part of the hotel bedroom accommodation.

The main entrance is under the central tower in Princes Street. The entrance hall, 52 feet by 26 feet by 22 feet high, gives access on the west to the grand staircase hall, which is 46 feet by 30. Both are finely designed with pillars, arcading and galleries, and the double staircase itself of white marble, with open arcading dividing it from the hall and with stained-glass windows, is one of the fine features of interior. As a prolongation of the entrance hall, carried across the central court is a reception hall, 58 feet by 20 feet and 20 feet high. This will be a handsome apartment, divided into six bays with

NEW IMPERIAL PATENT
SUPERFINE FLAX LINE.

The above article is now being manufactured and sold in large quantities for Greenhouse Sashes, Public-house Shutters, and other heavy work. The Manufacturers would recommend it for its strength, and the large amount of wear in it, consequent on its peculiar manufacture.

AUSTIN'S IMPERIAL PATENT FLAX SASH AND BLIND LINES (two Prize Medals awarded). The Manufacturers of the above articles particularly wish to draw the attention of the trade to their Imperial Patent Flax Sash Lines, of which they are now making six qualities, all of which they can strongly recommend, as they have given unqualified satisfaction to the trade for now over One Hundred Years, and the Proprietors continue to give their personal attention to the manufacture of these goods.

They also invite the particular attention of the trade to their IMPERIAL PATENT BLIND LINES, which are very superior to anything yet offered.

They can be obtained of all Rope-makers, Ironmongers, Merchants, Factors and Wholesale Houses in town and country.

N.B.—Please note that all our goods, as advertised above are labelled, either inside or outside, with our Trade Mark, "The Anchor."

pillars, well lighted and with a very ornate ceiling. It is expected to form a sort of central meeting place in the life of the hotel. The principal dining-room occupies the centre of the west front. It is 78 feet long and 28 feet wide. It is divided in two with sliding doors, so that in the slack winter season half can be shut off. North of the dining-room in the west angle will be a late breakfast and supper-room, and south of the dining-room will be the smoking-room and gentlemen's writing-room. These rooms will be about 30 feet square. Fronting Princes Street immediately to the west of the entrance hall will be a room 39 feet by 27 feet, designed for public meetings and dinners. On the east of the entrance hall, shut off from the public portions of the hotel, will be the first-class restaurant and the first-class public bar and wine shop, entered from Princes Street and North Bridge respectively. Under the first-class restaurant, below the level of Princes Street, will be the second-class restaurant; and behind these rooms will be the necessary serveries, lifts and other accessories. On the first floor the principal public rooms are again placed in the west wing. The grand staircase will be highly decorated, and the main apartment will be the double drawing-room, placed over the dining-room, in the west front, and measuring 53 feet by 28 feet. North of it will be the ladies' writing-room; and north of that again will be a suite of Royal apartments occupying the north-west angle, consisting of dining-room and drawing-room, two bedrooms, dressing-room and bathroom, and having a private corridor and hall. The royal drawing-room will be a fine room, 30 feet square, with fine oriel windows. There are other private suites on this floor, and a number of the principal bedrooms. Suites of apartments and bedrooms occupy the remaining floors. It will be observed that nearly all the public rooms have an outlook to the west. This gives them a magnificent view along Princes Street and the valley, taking in the picturesque ridges of the Old Town and the Castle. They will be strikingly decorated, a great point in their embellishment being the treatment of the ceilings. The principal apartments will have a height of 22 feet. Along the east and south sides, where it has been considered needless to give so much head-room, a mezzanine floor has been provided, and this floor, on the Bridge Street or east side, has been fitted up with offices, stockrooms and a large commercial-room, it being evidently the intention of the company to make a bid for a share of commercial business.

On the south side of the building has been provided the

accommodation for the railway offices. The entrance is from Bridge Street into a pillared octagon hall. On the main floor will be the general manager's department, occupying the eastern half, and the directors' room, occupying the western half. The Board-room will be a handsome apartment, 30 feet square, having two large oriel windows. The secretary's department is accommodated on the first floor, the solicitor's department on the second floor, and the chief engineer's on the third floor.

So much for the building above the street level. On the first floor below the street will be billiard-rooms, children's dining and play-rooms, hairdressing-rooms, a few visitors' bedrooms, the second-class restaurant, service-rooms and cellars, with, on the south side, the railway audit department. There is also a lower mezzanine floor for the accommodation of a portion of the staff, where rooms will be fitted up on the cubicle system. The second floor below the street will contain the kitchen and the accessories which this important department of a large hotel requires. The principal kitchen will be 44 feet by 31. There will also be here a despatch room, distributing store, servants' hall and sleeping rooms, and an important feature—a general arrival hall, 46 feet by 28 feet, for passengers arriving by train. Access will be had to this hall from the station platform by hoist or stair. The third floor below the street will provide male servants' sleeping accommodation, the machinery for the heating and ventilating of the hotel, the hydraulic machinery for the lifts, and the boilers for driving it; also the laundry departments and a very completely arranged bakehouse. Finally, on the fourth floor below the street will be boiler-rooms, coal-cellars and paper stores for the railway offices. In all the accommodation will be as follows:—Public apartments, 21; private parlours, 14; bedrooms and dressing-rooms, 295; sitting-rooms and bedrooms for hotel officers and servants, 146; stock-rooms, 10; and administrative apartments, 262—in all 748, not including the shops and offices in the North Bridge and the offices of the North British Railway Company. The estimate includes sums for machinery and plant which the company already possess, so that, excluding these, the sum of 221,000*l.* stated would be somewhat reduced.

The other architects who were invited to send in competitive designs were Dr. Rowand Anderson, Messrs. Dunn & Findlay, Edinburgh, and Messrs. Thomson, Leiper, and Messrs. Burns, Son & Campbell, Glasgow. Messrs. Dunn & Findlay were placed second in the competition.

"OPTIMUS" MAGIC LANTERNS SUITED FOR DRAWING ROOM AND LECTURE HALL.

Limelight may be adapted without alteration at an extra cost of 18s.

Each Magic Lantern is efficient for exhibitions. The Lens gives crisp definition, being a superior Achromatic Photographic Combination with rack and pinion. It is fitted to a telescopic lengthening tube, so gaining increased focal accommodation. The Condenser is composed of two plano-convex lens of 4 inches diameter. The refulgent lamp has 3 wicks, yielding a brilliantly illuminated picture. Each is complete in box. Pairs for dissolving arranged in one Box at same prices. Lever Dissolver, 8s. 9d.

Superior Japanned Metal Body, 30s.

Student's Lantern (to take demonstrating tank) with Brass Sliding Tubes, 40s.

Russian Iron Body, Brass Sliding Tubes, 45s.

Perforated Russian Iron Body, Brass Sliding Tubes, 50s.

Mahogany outside Body, Two Panelled Doors, Brass Stages and Sliding Tubes, 82s.

Mahogany Body, Brass Stage and 8 draw Telescopic Tubes, 105s.

RECLAMATION OF THE ROMAN CAMPAGNA.

WE have several times noticed the efforts of the Italian Government to insure the sanitation of the Campagna Romana. The benefit that the inhabitants of the Campagna, as well as the inhabitants of the suburban zones and Rome itself, have derived therefrom, have been accurately ascertained by means of special investigations and statistics. On the occasion of the International Medical Congress which was held in Rome in the month of March, 1894, the Ministry of Agriculture presented the results of the investigations along with some tables which showed graphically the degree of malaric infection in various parts of the Campagna. These investigations began in 1888 with the intent of establishing the number of malaria fever-stricken amongst all those persons employed in field work with fixed residence in the tenements existing in the territory. The number per area was ascertained of the agricultural population spread over the country to the right and left of the Tiber separately, distinguishing the inhabitants of the Campagna from those of the suburbs, but all residing permanently on the single tenements. The contingent of malaria-stricken inhabitants during each of the two periods, 1888-90 and 1891-93, was also ascertained and arranged according to the degree of density of population and to the respective proportion for every 1,000 inhabitants.

The amelioration in the sanitary conditions of the district in question during the last three years in comparison with the results of the previous period is self-evident, both as regards the percentage of the fever-stricken as well as the number of persons attacked by the "perniciosa" form of fever, especially in those places where, besides a thorough regulation and a proper preservation of the principal ditches carried out under official control, additional improvements, hydraulic and agricultural, were effected by private landowners, and where the supply of drinkable water was provided.

The percentage of cases of malaric fevers which during the first of the said triennial periods fluctuated from a minimum of 166 per 1,000 in the suburban portion of the zone on the right side of the Tiber, and a maximum of 333 per 1,000 in the Campagna properly called on the left side of the river, fell to a minimum of 105 per 1,000 in the same suburban portion to the right, and to a maximum of 218 per 1,000 in the Campagna on the left of the river.

The "perniciosa" fevers, which during the first three years amounted to 108, of which 34 cases on the left of the Tiber, in

the three years 1891-93 fell to only 41 cases, of which 23 on the right and 18 on the left of the Tiber.

The Italian Government have received some help in their efforts in that direction from the Rome municipality, who placed at the disposal of landlords 100 "oncie" of marcia water (440,000 gallons per diem) at a reduced cost, which can be had at a pressure of from 40 mètres to 65 mètres (43 yards to 71 yards) from various centres of distribution. The municipality have also placed along the aqueducts fountains and troughs for free public use.

The co-operation of landowners if not absolutely deficient is certainly slack in spite of the law; but there are exceptions, especially the Prince Torlonia, who has contributed to provide the Campagna with an important supply of water collected from several springs, which by means of hydraulic power is made to rise to a reservoir placed over one of the old towers called the "Cecchignola," obtaining in that way a pressure of 80 mètres (87 yards). From that level water can be distributed to higher grounds on the left of the Tiber, for which the pressure of the marcia water (71 yards) is not sufficient.

The questions bearing upon the agricultural advance of the "Agro Romano" seem to excite greater public interest in comparison with past indifference, but as regards practical results there is very little to record. The members of parliament for the province have formed themselves into a sort of agrarian group. Meetings are held, resolutions are adopted, appeals are made for legislative or Government aid, but only two points bearing upon the subject need be noticed.

First, with regard to corn-growing, which is the most natural as it is the traditional staple production of the Campagna. In the month of April, 1894, a thorough representative agrarian congress was held in Rome, and on that occasion it was repeatedly and authoritatively asserted, and the matter was made the subject of a formal resolution, that under the present conditions of agriculture in Italy corn-growing resolves itself into a dead loss as long as the price of corn will remain below 25 lire (1*l.*) per quintal, and considering that the fall in the price cannot stop, owing to the special conditions of exporting countries, but that, on the contrary, the fall is persistent, the congress demanded that the import duty on foreign corn be fixed at not less than 9 lire per quintal.

The Rome municipality at the same time adopted a resolution inviting Parliament, in the interests and for the protection of agriculture and of national labour, to vote an increase of the import duty on corn beyond the limit proposed by Government.

(7 lire). Parliament, however, resolved to limit the duty to only 7 lire, being an increase of 2 lire per quintal on the former rate.

Another subject which has attracted some attention is the movement in favour of the sugar beetroot cultivation in the "Agro Romano," which would tend to gradually transform at no great expense the system of tillage by alternating two different crops on the same soil, especially so as it is asserted that in France and in Belgium the average yield of wheat in lands under beetroot has notably increased. The number of cattle could also then be augmented, inasmuch as the beetroot supplies two important qualities of fodder, the leaves and the waste pulp after manufacture.

Promising schemes have been made as regards the adaptability of the soil, probable production, cost thereof, sale price and increase of profits to the agriculturist, but they need testing, and the production of beetroot necessitates the erection of sugar factories. After the unsatisfactory results obtained by the factories which were started some years ago at Rieti and at "Castellaccio" it is not very probable that any similar attempts will be made, especially as those amongst the banks who were customary to help industrial undertakings are now helpless, and there is no means of forming a company with sufficient capital in the country. Therefore the movement in favour of the beetroot cultivation in the "Agro Romano" seems, for the present at least, destined to remain a desideratum.

THE ELECTRIC LIGHTING OF EDINBURGH.

A LECTURE by Professor Kennedy, the consulting engineer of the Edinburgh Corporation in the electric lighting of the city, was read to the members of the Edinburgh Literary Institute by the resident engineer. Professor Kennedy explained generally the method of obtaining electrical energy, emphasising the fact that electrical energy was not created, but was only made available by altering its pressure. The earth was the great storehouse of electrical energy, and just as a pump raised water from a reservoir and delivered it at pressure through pipes by which it was distributed over a house, so the dynamo delivered electrical energy under pressure, and it was distributed, as water or gas was distributed, throughout the city to such as required it. Professor Kennedy described and illustrated the methods by which the electrical energy would be generated at the Torphichen Street station; by which it would be sent into

the various districts of the city through trunk mains to the feeding mains, which were either armoured cables laid in the ground or bare copper conductors carried on insulators in culverts; by which from the feeding mains it would be carried to the distributing mains, which were insulated cables laid in fireclay conduits, and by which from the distributing mains it would be made available for public or domestic supply. Touching on the cost of electric lighting, he indicated that with the Board of Trade unit of electricity at 6d., and capable of lighting a 16 candle-power lamp for seventeen hours, and with the lamp costing 1s. 3d., and having a life of 800 to 900 hours, the cost of the light would be about one-third of a penny per hour, which was practically half what it cost two years ago. With gas at its present price, electricity would not be more expensive, provided it was properly switched, so that several lamps would not have to be lit when only one was required, and provided also the light was economically used and not kept burning needlessly. As showing the demand for electric lighting, he mentioned that in London the rate of increase had been 160,000 lamps per annum during the past three years.

FIRE AT BUCKSKIN HALL.

BUCKSKIN Hall, otherwise known as Dacre Lodge, at Cockfosters, between Barnet and Enfield, was on Friday, 8th inst., destroyed by fire. It dates back to Charles II's reign, and was probably a lodge of the forest which formerly surrounded it. The present occupier is Mrs. Gladstone, widow of Mr. Robert Gladstone, of Manchester, cousin of the late Premier. The fire broke out soon after midnight at the top of the house, and, owing to lath and plaster partitions, spread the more rapidly. The fire-engine from Trent Park (the adjacent seat of Mr. F. A. Bevan) did good service until the arrival of those from Barnet and New Barnet. The water-supply was obtained from a pond immediately in front of the mansion. The plate, drawing-room and dining-room furniture, and a library were rescued from the fire, but much was destroyed. The left wing, which is of later date, though damaged by smoke and water, was saved. The outbreak is thought to have originated through a heating-flue. It is estimated that damage to the amount of about 10,000l. was done. Fortunately the place was insured. On an upper wall there was a fresco outline depicting a hunting scene of the time of James I.

KILBURN WIRE WORKS, 288 HIGH ROAD, KILBURN

THE RUSSIAN IRON INDUSTRY.

AN elaborate report on the iron industry of European Russia has been prepared by Mr Hugh O'Beirne, Third Secretary at the British Embassy, St. Petersburg. The subject is most difficult, owing to the absence of official information. The following are Mr. O'Beirne's conclusions:—

The chief iron-producing regions of European Russia, named approximately in the order of their importance, are known as the Urals, South and South-Western Russia, South Poland, Central Russia (or Sub-Moscow), North Russia and South Finland iron districts. There is also a limited production, chiefly of magnetic iron, in the Elizabethpol district of the Southern Caucasus.

European Russia, including the Caucasus and Finland, has an area of 2,095,500 square miles, and produced in 1892 some 1,060,000 tons of pig-iron and cast-iron, 480,000 tons of wrought-iron and 516,000 tons of steel. That is to say, with an area over sixteen times that of Great Britain, over nine times that of Germany and that of Austria-Hungary, and about ten times that of France, her iron production, taking the output of pig-iron as a test, was less than one-seventh that of Great Britain, less than one-fourth that of Germany, half that of France, and only slightly more than that of Austria-Hungary.

The consumption of pig-iron per head of population in Russia was in 1891, 22·16 lbs. In Great Britain it reached in 1890, 449 lbs.; in Germany, 242 lbs.; in France, 97 lbs.; and Austria-Hungary, 61 lbs.

The principal causes to which must be referred this extreme comparative lowness of production and of consumption per head of population may be resumed as follows:—On the one hand the general demand for iron is small, by reason chiefly of the backward state of manufactures, little application of machinery to agriculture, smallness of railway traffic, &c., and it is smaller even than it must necessarily be under present conditions of industrial development, because in Russia wood replaces iron in a large variety of uses, of which house-building, bridge-making, cart and sledge-making are perhaps the most obvious in importance. On the other hand, the general cost of production is high, because the riches of iron, though great, are moderate in relation to the vast extent of the empire; they are in large part situated at immense distances from the centres of consumption; there is a deficiency of coal of the requisite quality in the vicinity of iron, and the methods of production are not always the most recent

or the most economical. Lastly, the production is checked by the limited supply of available capital.

Considered in greater detail the conditions of the demand for iron and its supply may be thus described:—

The general demand for iron in the shape of wrought-iron and steel centres in five principal regions, characterised by comparative density of population and industrial developments:—

1. Central Russia, including (1) the Moscow industrial region with the towns of Moscow, Tver, Vladimir, Kolomna, &c., having a larger production of manufactured and metallic goods than any other region of Russia; and (2) to the south and south-east of this region, the black soil region, of which the chief product is grain, but which includes the manufacturing towns of Tula, Orel, &c.

2. The Baltic region, with St. Petersburg, Riga, Libau, ranking next to the Moscow region in importance of manufactures.

3. The industrial region of Poland, with the towns of Warsaw, Lodz, Kovno, &c., the third manufacturing region of Russia and the most densely populated.

4. The region of South Russia, bordering on the Black Sea and Sea of Azov, with Odessa, Rostov, Nikolaiev, &c., in association with which may be mentioned the towns of Kieff, Poltava and Karkov lying further north.

5. The eastern metal and grain-producing region lying to the east of Nijni Novgorod, with the towns of Kazan, Perm, Samara, &c.

These centres of demand are thus supplied:—

Central Russia obtains an important part of its wrought-iron and steel ready made, chiefly from the Urals, and in smaller quantities from South Russia, Poland, St. Petersburg, and abroad; makes the remaining part, principally from pig-iron obtained from inferior local ores; these, however, are supplemented by a small quantity of pig-iron and ore obtained from the Urals and South Russia.

The fuel consumed in smelting is coal sent from the Donetz, paying freightage of 12 c. per pound; and in other processes of iron making and in steel making is Donetz coal, expensive local wood fuel, and naphtha from Baku.

The Baltic region makes its wrought-iron and steel for the most part from imported pig-iron (five-sixths of which are British) and partly also from pig-iron obtained from the Urals; a considerable quantity of wrought-iron and steel is imported from abroad, and received from the Urals and Central Russia

SHORLAND'S PATENT COMBINATION OPEN FIRE-PLACE MANCHESTER STOVE

Made in various Designs and Sizes, with Tiled or Iron Sides, Single or Double Fronted, and with Ascending or Descending Smoke Flue.

and Poland. This district works on coal imported from England, subject to a duty of 1 c. per pound (1s. 11½d. per ton).

The Polish region makes most of its wrought-iron and steel from pig-iron which is smelted from poor and expensive local ores on coal and coke imported at a duty rate of 1 c. and 1½ c. per pound (1s. 11½d. and 2s. 11½d. per ton). These ores are supplemented by some 12,100 tons pig-iron imported from Austria and Germany. There is a considerable import of wrought-iron and steel, principally from Germany.

The South Russian is the only district which produces its wrought-iron and steel under normally favourable conditions, uniting rich iron deposits with an abundance of good local coal.

The eastern district has rich deposits of ores throughout the Urals and in the Governments of Perm and Viatka, but conducts its smelting and other processes chiefly on wood fuel.

In general, therefore, the demand for wrought-iron and steel is met by a supply produced under very unfavourable conditions. The values of the products stand correspondingly high. A rough practical measure of the relative expensiveness of iron to the general consumer in Russia and, for example, Great Britain, is supplied by the proportions borne in each country by the price of pig-iron to the average wages of labour in some of the more important industries. The wage of a cotton weaver in Russia ranges according to locality, &c., up to a maximum of 33 r. per month. Taking the wage at 30 r. and the price of pig-iron in the Moscow district at 60 c. per pound, 1 ton of pig-iron represents to the artisan about five weeks' earnings. If we take the weekly wage of a Huddersfield weaver at 17. 4s., 1 ton of English pig-iron represents to him less than one week's earnings, or a sacrifice less than one-fifth of that which the Russian consumer must make for the same weight.

In so far as the present smallness of the demand for iron results from the backward state of manufactures and similar causes, we may expect with the increase of population and the development of industries a corresponding expansion of the iron production. So far as the demand is checked by the substitution of cheap wood for expensive iron, the question of the increasing scarcity of wood has an important bearing on the future of the iron industry. Over 30 per cent. of the area of European Russia (including the Caucasus, but not Finland) is forest. But that fact gives no correct idea of the extent to which consumers throughout Russia have wood at their disposal. For while the northern districts have some 54 per cent.

of forest area, and the Central Volga and lake districts 30 per cent., the Moscow trading regions, Poland and the Baltic provinces have only from 23 to 17 per cent. of forest, and the black soil steppes practically none. Less than half of Russia is rich in forest, one-fifth is poorer than Germany or France, and one-eighth has scarcely any. There is much waste arising from mismanagement in private forests, though subject to a limited Government control.

The tariff has been directly instrumental in bringing into existence some of the more important branches of the iron industry, notably the pig-iron industry in Poland and the iron and coal industry in South Russia. It is not equally clear within what limits the industry is still dependent on a continuance of protective policy. The principal feature of the South Russian district, the rolling of steel rails, is that branch of its production which is absolutely protected against foreign competition. It is probable that if import duties on iron were removed, the Polish and Moscow districts would reduce the smelting of inferior and expensively obtained local ores, and would produce wrought-iron and steel on cheaper imported pig.

The tariff, moreover, obviously increases the expenses of production of wrought-iron and steel in the Baltic region by raising the cost of foreign pig-iron and coal, and in Poland by raising that of coal and coke; and generally throughout Russia by increasing the cost of machinery and plant, which, in the present condition of the industry must be procured from abroad.

During the years 1881-92 the output of pig-iron more than doubled, rising from 460,000 tons to 1,060,000 tons, and the combined output of wrought-iron and steel has risen from 575,000 tons to 1,000,000 tons. During the closing years of the period the production rose quickly, thus marking the decisive expansion of the home industry at the expense of imports. Thus pig-iron rose at the rate of 16,000 to 24,000 tons a year up to 1886, after which the yearly increase is 48,000 to 80,000 tons, and from 1889-90 to 177,000 tons. Steel fell after 1881, an abnormal year, owing to the issue of great Government orders for steel rails; shows no advance from 1883-89, but between 1889-92 rises from 253,000 tons to 516,000 tons. Wrought-iron is stationary from 1884-88, and rises constantly up to 1892.

A corresponding movement is noticeable in imports of pig-iron, which from 1886-91 fell from 258,000 tons to 80,000 tons, and of wrought-iron, which rose up to 1890, and from 1890-92

Wrought-Iron Work.

Stained Cathedral Glass, and any other Interior Work.

fell from 93,000 tons to 49,000 tons. The import of steel rose up to 1890, and from 1890-91 fell from 16,000 tons to 12,900 tons.

While the gross production of steel rose from 1882-92 from 242,000 tons to 516,000 tons, the manufacture of steel rails shows little change (153,000 tons in 1882 to 182,000 tons in 1892). Nearly half the total weight of steel prepared in Russia is used in the manufacture of steel rails.

The countries which were the largest senders of pig-iron, wrought-iron and steel in 1892 were:—

Country.	Quantity.		
	Pig-iron.	Wrought-iron.	Steel.
	Tons.	Tons.	Tons.
Great Britain. . . .	62,130	7,500	7,200
Germany	9,700	24,800	4,700
Belgium	1,500	4,500	750
Sweden	1,000	1,630	200
Austria	300	110	310

The great bulk of imported iron of all descriptions goes to the Baltic provinces and Poland.

Great Britain provides some five-sixths of the total import of cast-iron. The larger part of the British pig-iron goes to the Baltic provinces; a small proportion to Poland, *via* the Vistula. The pig-iron most quoted is Shott's No. I and No. III for foundry purposes and hematite white and grey for steel purposes. The German pig-iron is consigned almost wholly to Poland across the western frontier. British wrought-iron and steel goes chiefly to the Baltic provinces and in lesser quantities to South Russia. The descriptions mostly imported are plates, flat, round, square, angle and T and I-iron, and common spring steel. The German and Austrian wrought-iron and steel go chiefly to the Polish district and also to Odessa, Kieff and other South Russian towns. By far the largest consignments are of iron in bars and assorted, and of iron up to 25 B.W.G.

The total import of castings in the rough was, in round numbers, 1,050 tons, consigned chiefly to the Baltic ports (320 tons), and across the German frontier (430 tons). The chief senders were Germany (540 tons) and Great Britain (310 tons).

The total import of steel rails was 2,000 tons. The largest

senders, Belgium (1,100 tons), Germany (460 tons) and Great Britain, which sent 130 tons to Batoum and half a ton to Baltic ports.

There were exported from Russia in 1892 some 200 tons of pig-iron, 5,000 tons of wrought-iron and 400 tons of steel. About 600 tons of sheet-iron went to England.

PATENTS.

[This List of Patents is compiled specially for this Journal by Mr. G. H. Rayner, of the firm of Rayner & Co., Consulting Patent Agents, 37 Chancery Lane, London, W.C., from whom all particulars and information relating to Patents may be had gratuitously.]

APPLICATIONS FOR PATENTS.

2486. Peter Treadgold, for "An improved appliance to be affixed to doors, window sashes or casements to prevent the entrance of wind, snow, dust, or similar inconveniences."

2582. Henry Sutcliffe, for "Improvements in chimney-pots or cowls."

2600. Frederick Hughes and John Cooper Webb, for "Improved automatic door and holdfast hook."

2603. William Nicol, for "Improvements in and relating to fastenings connected with the sliding sash-frames of windows."

2694. William Ingham, for "Improved means of ventilation as applied to window sashes."

2703. Herbert Henry Green, for "Improvements in rising butt hinges and in other hinges for doors and vertically-hinged windows."

2744. Thomas Robinson, for "An improved window or sash fastener."

2791. Henry Vaughan and Samuel Smith, for "Improvements in night latches constructed to be operated by keys which are not passed through the thickness of the doors to which the latches are fixed."

2845. Michael Bohn, for "Improvements in roofing tiles."

2865. John Shanks, jun., for "Improvements in discharge apparatus of water-closet or other cisterns."

TO INVENTORS.—Patents for Inventions, Trade-marks and Designs secured; every assistance given to inventors. Specialists in Building matters. Information free.—Messrs. RAYNER & Co., Patent Agents, 37 Chancery Lane, London, W.C.

WINTER, WARMTH AND COMFORT.

HEATING AND VENTILATING APPARATUS. GRUNDY'S SPECIALTY. PURE WARM AIR.

UPWARDS OF ONE THOUSAND TESTIMONIALS RECEIVED.

PURE WARM AIR AS SUPPLIED TO

Truro Cathedral; Londonderry Cathedral; Sherborne Abbey; Kilmore Cathedral; Stanley Cathedral, Falkland Islands; Cardiff Catholic Cathedral; the Queen's School Chapel, Eton; Cork Asylum; Leicester Asylum; and to upwards of three thousand Places of Worship; and a great number of Mansions, Houses, Hotels, Hospitals, Schools, Warehouses, Factories, Workhouses; Cork Law Courts, &c., &c.

Sir WILLIAM BROADBENT encloses cheque for the "GRUNDY" HEATING APPARATUS supplied to his house, and is glad to say that it has proved very satisfactory for warming and ventilating as required. The principle of the apparatus is most excellent.

To Mr. Grundy.

PROFESSOR TYNDALL writes:—

Dear Sir,—My house being so well provided with grates and flues for the generation and distribution of pure warm air, I have been thus enabled to spend my winters in England instead of on a foreign shore.—Yours very truly,

JOHN TYNDALL.

Dear Sir,—I have much pleasure in informing you that we have found your HEATING APPARATUS a great success in our new Epidemic Hospital, which consists of a two-storey building, each storey containing two large wards, a smaller isolation ward, and two nurses' rooms. It is easily managed, does not cost much for fuel, and the air entering is most pleasant, warm, and free from smell. It is with the full concurrence of the Managing Committee I give you this testimonial.

Yours faithfully, JOHN MARSHALL DAY, Registrar and Resident Medical Officer.

84 Brook Street, Grosvenor Square, W.: December 8, 1893.

October 24, 1893: Hind Head House, Haslemere.

Fever Hospital and House of Recovery, Cork Street, Dublin: October 26, 1894.

THE

Architect and Contract Reporter.

NEW READING CASE.

To Librarians of the Public Libraries and Reading-rooms.—A new handsome Reading Case can be supplied at a nominal charge of 2s., by post 2s. 6d., on early application to the Publisher, 175 Strand, W.C.

SPECIAL NOTICE TO THE TRADE AND OTHERS.

[Extract from a lecture on Architects' Libraries by Professor T. Roger Smith, F.R.I.B.A., at University College, October 10, 1893.]

"Lastly, let me recommend the back volumes of the professional journals. In the course of years all sorts of architectural topics come up in the public press and before the professional societies, and if you hunt through the indexes of these publications when you are seeking for information which eludes you in books, you will often be rewarded."

There has been a considerable demand for the back numbers of *The Architect* during the last three or four months, which we have no doubt has arisen from the remarks made by Professor Roger Smith, as contained in the above quotation; but the consequence has been that our stock of back numbers is getting very low, and consequently, in future, the charge for back numbers of previous date to January 12, 1894, will be 6d. each.

A few of the back volumes may still be had, price 12s. each.

EDITORIAL NOTICES.

The authors of signed articles and papers read in public must necessarily be held responsible for their contents.

No communication can be inserted unless authenticated by the name and address of the writer—not in every case for publication, but as a guarantee of good faith.

Correspondents are requested as much as possible to make their communications brief. The space we can devote to Correspondence will not usually permit our inserting lengthy communications.

TENDERS, ETC.

*** As great disappointment is frequently expressed at the non-appearance of Contracts Open, Tenders, &c., it is particularly requested that information of this description be forwarded to the office, 175 Strand, London, W.C., not later than 5 P.M. on Thursdays.

WINSOR & NEWTON'S

"Waterproof"

INDIAN INK.

This new preparation—made from genuine Indian Ink—has been introduced to meet the requirements of those Artists, Architects and Designers who wish to lay washes of colour over drawings in ink.

Unlike many so-called Indelible Inks, "Waterproof Indian Ink," when dry, will be found absolutely unaffected by subsequent wetting.

VARIETIES.

A SPECIAL meeting of the Trustees of the Manchester Royal Infirmary has been held to consider a proposal for enlarging the present buildings. The board of management favoured a plan for increasing the accommodation to the extent of 100 beds, by adding a wing to each end of the Infirmary. This plan, Dr. Renaud stated, had met with the almost unanimous approval of the board. He accordingly moved a resolution approving the scheme as the most suitable and efficient means for meeting the necessities of the case. Mr. Alderman King seconded the resolution. Mr. Francis Greg suggested an adjournment of the meeting to give time for fuller consideration. Mr. W. Brockbank put forward an alternative plan—the rebuilding of the Infirmary on the present site, thereby providing Manchester with an hospital worthy of the city, architecturally and in all other respects. The amendment found favour with the meeting, but in order to test the opinion of the trustees generally a poll was demanded.

THE Local Government Annual for 1895, published at the Local Government Journal Office, is now to hand, and, as usual, is full of useful information relative to local government, the constitution of metropolitan and county local authorities, &c., and being compiled from data supplied from official sources, may be taken to be as reliable as a directory possibly can be.

AN inquiry under the Housing of the Working Classes Act, 1890, has been held at the Council House, Birmingham, into the scheme of the Corporation for dealing with insanitary property in Milk Street and Little Ann Street. The area of the site is 4,030 square yards, and it is estimated that it will cost the Corporation 5,500*l.* to acquire the property, while the

value of the land, when the buildings have been pulled down, is put at 3,350*l.* The Corporation do not propose to take any steps to secure the erection of workmen's dwellings in the place of those pulled down, as there is believed to be no lack of houses in the neighbourhood.

THE next monthly meeting of the London and Provincial Builders' Foremen's Association will be held to-morrow (Saturday) evening, at the Memorial Hall, Farringdon Road, E.C.

THE twenty-eighth annual general meeting of the Artisans, Labourers and General Dwellings' Company, Limited, will be held at the Westminster Palace Hotel, Victoria Street, Westminster, on Thursday, the 7th inst., at 12 o'clock, to present the report and balance-sheet for the last year, and to transact the ordinary business of the company and elect directors and auditors.

AT the meeting of the Yorkshire College Textile Society, Leeds, Mr. C. C. Dodgshun read a paper on the production of new patterns. He touched on the importance of constantly producing new patterns. The designer, by being kept working in the mill, had no opportunity of seeing the new styles. Designers ought to visit the markets themselves, and personally ascertain what was required by customers. The fact that designers had heretofore had little or no intercourse with the buying community was a state of things that ought to be remedied at once.

TRADE NOTES.

MESSRS DONALD & SIME having, on the 18th inst. resigned their respective appointments as consulting engineer and works manager of Robert Boyle & Son, Limited, with whom they have been for over eleven and twelve years respectively, have commenced business as ventilating, heating and sanitary engineers.

THE Secretary of State for Foreign Affairs has received through Her Majesty's Consul at Cadiz information to the effect that the Seville Waterworks Company, Limited, will receive up to March 8 tenders for the supply of material and construction of a foot-bridge over the river Guadalquivir. Printed specifications, estimates and conditions, may be seen at the Commercial Department of the Foreign Office, S.W., between the hours of eleven and six.

ASPINALL'S WAPICTI

The only perfectly successful Washable Distemper Paint. Guaranteed to stand on New Plaster. Proved and adopted by London County Council and Principal Public Bodies at Home and Abroad.

Architects and others interested should inquire as to this before specifying for New Work.

ASPINALL'S ENAMEL, LIMITED,
NEW CROSS, LONDON, S.E.

FOR the ventilation of Martyrs' Church, Paisley, on which extensive alterations and improvements are being carried out (Mr. T. G. Abercrombie, architect), special attention is being given to the ventilation. The "Climax" patent direct-acting invisible roof ventilators are being used for the purpose of extracting the vitiated air, and have been supplied by Messrs. Cousland & Mackay, the sole manufacturers, Glasgow, and London.

THE Children's Hospital, Paddington Green, is being warmed and ventilated by means of Shorland's patent Manchester stoves, with descending smoke flues, the same being supplied by Messrs. E. H. Shorland & Brother, of Manchester.

THE Hope Trustees have accepted the tenders of Mr. Thomas Telford, mason, Langholme, and of Mr. Matthew Knox, joiner, for the erection of the new hospital at Langholme, of which Mr. Wood, London, is the architect.

THE Bedford Economic Fire Company are showing at their premises in New Oxford Street (No. 87) their newly-patented fire (Wilson's Patent Economic Kitchen Fire, to give it its full appellation), which deserves a visit of inspection from all architects, householders and housewives. This patent can be applied to every existing kitchen, of which it greatly increases the efficiency, at the same time reducing the consumption of fuel to a really wonderful extent. These desirable results are obtained by means as simple as they are efficacious, namely, by passing all air through the bottom of the shallow fire before it reaches the flues, from which all cold currents are rigorously excluded, thus causing perfect combustion and the almost entire consumption of smoke, at the same time rendering the small amount of fuel which the grate contains amply sufficient to heat the ovens, hot-plate and boiler to any desired degree, and with a rapidity which, by the old system, was scarcely attainable, however large the fire. The company claim to save by this apparatus from 50 to 75 per cent. in the consumption of fuel, and we are pleased to be able, by practical test, to say that this claim is in no wise exaggerated, and that the patent is a most efficient and valuable one. As we have mentioned above, it can be inexpensively and expeditiously applied to any existing kitchen. As a valuable complement to the patent fire, Wilson's patent boiler has the following advantages, *i.e.* it presents double the ordinary amount of heating surface to the fire, thus insuring greater rapidity in heating; it needs clearing less frequently and requires no setting.

ARCHITECTS IN CARDIFF.

THE annual dinner of the Cardiff, South Wales and Monmouthshire Architects' Society was held on February 21. In responding to the toast of the Society, Mr. E. M. Bruce-Vaughan, the president, asked who was responsible for the defects of Cardiff architecture? The borough engineer by suggesting the new by-law, "a separate drain to each house," had endeavoured to cope with one defect, and as a Society they heartily agreed with that by-law. Then, who were responsible for the defects? The County Council, who gave the borough engineer—a man of the highest qualifications himself—an inadequate staff, and also put him in direct competition with private industry by making him the architect of market buildings, sanatoriums, hospitals, police-stations and the like. Why should a hospital, a sanatorium, a market-place or a police-station be designed by a borough engineer and so throw a still greater burden on already overburdened shoulders, and at a time when there many local architects quite capable of designing and efficiently superintending buildings of this kind who had far too little to do? Architects at a distance seemed to think that Cardiff was a veritable Land of Goshen, but how disappointed they were when they had learned by experience that so little was left for private and individual industry because of the estate system and because the municipal governors were the municipal architects as well. Continuing, the President accounted for the absence of the science of architecture in their buildings at Cardiff by pointing out that the houses and villas were built by the score for the people instead of the individual building the house for himself. They were built for the sake of the profit to the speculator. There was no other object in view, and he did not know of any town of the size where the villa and residential architecture was so poor as it was in Cardiff.

Mr. W. Harpur said that there had been 1,000 houses per annum built in Cardiff for the last ten or eleven years, and he mentioned that since he had been appointed borough engineer he had performed more work than the whole of his predecessors.

Mr. W. H. D. Caple proposed "The Kindred Arts and Sciences," to which Mr. E. W. Waite responded, and other toasts followed.

The public matters with which the architect's profession is concerned in South Wales have been recently exciting some

ADVANTAGES.—By the use of this Patent Fanlight Opener, a Sash can be opened to any required distance, and the action of loosening the cord causes the cam to clip chain and hold securely.

The Chain, made in Copper, are impervious to all atmospheric influences and being quite flexible, the Opener works with the greatest ease. It is suitable for any size sash.

The Patentees have every confidence in calling the attention of Architects, Builders, Ironmongers and the trade generally to their new Patent Window Openers, as possessing advantages over all other Fanlight Openers in the market.

Working Models of the above and other Specialities may be seen at our new Showrooms, 57 HOLBORN VIADUCT, E.C.

amount of interest and comment in circles even outside the profession itself. It was expected in some quarters that reference would be made at the dinner of the Architects' Society, held in Cardiff on Thursday night, to the burning question of the new museum and art gallery, but in this the public was disappointed. Our own comments upon this matter a week or two ago indicated that the subject is one not of limited importance, inasmuch as the question seems to involve the honour of the Corporation as well as the individual rights of an individual. The absence of Mr. Edwin Seward, the immediate past president of the Society, from Thursday's dinner was a conspicuous absence; and inasmuch as his name did not appear amongst those who had sent letters intimating their inability to be present, the matters in dispute between that gentleman and the majority of the Society assumed a critical phase. In order to obtain an explanation of the whole position, a representative of this journal waited last night upon Mr. Bruce-Vaughan, the president of the Architects' Society, by whom he was very courteously received.

"The question involved," said Mr. Vaughan, "is simply whether Mr. Seward has been retained by the Corporation as architect for the new museum and art gallery in Park Place. Mr. Seward says he has; members of the museum building committee, including Dr. Chas. Vachell, say he has not. It is, indeed, affirmed that the committee has not yet even met, and therefore could not have appointed an architect. Then, Mr. E. W. M. Corbett, architect to the Bute estate, states distinctly that the ground in Park Place was let or leased to the Corporation on the understanding, or with the provision, that the designs should be thrown open to public competition."

"But to go further back, Mr. Vaughan. Is it not the fact that Mr. Seward was appointed, under resolution of the Council, architect of the library extension, which included at that time the museum and art gallery?"

"Yes, that is so."

"Then, in your opinion, a change of site necessarily involves a change of architect?"

"No, personally I do not think it should necessarily involve a different architect; but remember what members of the committee—who are the employers in this case—emphatically say, that no architect has been appointed."

"In the absence of a resolution of the Corporation rescinding the previous resolution, would you not consider that it was intended the same architect should be employed for the new site?"

"Well, yes, I should be inclined to think so. At the same time, the circumstances of each case must be weighed. Supposing I, as a builder or owner, modified my original plans, and paid my architect his full fees for the work executed and part fees for the portion not carried out, I should feel myself at liberty to employ any architect I chose if I determined to complete the first plan."

"Would you, if you had again had the assistance of the same architect to carry out your second thoughts?"

"Oh no."

"Then is it not true that Mr. Seward has done work in connection with the new site of the museum?"

"I believe he has reported upon the capacity and suitability of the new site, but only in an honorary position—as a member of the museum committee."

"Is it customary for architects to do work honorarily for a public body like the Corporation?"

Mr. Vaughan (smiling): "I can't say. Some people do it."

"Do you think Mr. Seward would have at least a moral claim if he had done any work whatever for the new site, especially in view of his position as architect under the original scheme?"

"Yes, I think he would have a moral claim, and if Mr. Seward can establish that claim I, for one, and I am sure the majority of the Society members also, would back him up in it. But Mr. Seward has persistently declined to attend our meetings to discuss the subject, while we have the statements of Dr. Vachell and Mr. Corbett against the position he takes up."

"Did Mr. Seward write you a letter explaining why he would not be present at the dinner last night?"

"Yes. I also received other letters of apology for non-attendance from other gentlemen, but I did not mention the fact at the dinner. Only those gentlemen who had written to Mr. Caple were thus named. In any case it was not desirable to make known the contents of the letter, because they are of a controversial nature, and not calculated to promote that harmony which should reign at the festive board."

TOTTENHAM COURT ROAD
LONDON. W

CARVED OAK AND ANTIQUE DEPARTMENT, No. 204 TOTTENHAM COURT ROAD.

"Do you feel at liberty to show me the letter?"

"No. I think it ought to come first before the Society. I may tell you, however, that I have replied to-day to Mr. Seward, saying that I will call a meeting of the Society any time which may suit his convenience to discuss the matter, provided he will promise to be present."

"Finally, do you object to state how much the museum retainer will be worth to the architect?"

"No; I should say somewhere about 600/."

In view of the refusal of Mr. Bruce-Vaughan to divulge the contents of Mr. Seward's letter to him on the subject in dispute, our representative pursued further inquiries, which resulted in his obtaining a copy of that interesting document. It is as follows:—

My dear Vaughan,—I am writing to express regret at being unable to be present at the annual dinner of the Cardiff, South Wales and Monmouthshire Architects' Society. The course which has been followed in endeavouring to so influence the authorities as to cause me to be deprived of the position of architect to the Cardiff Museum and Art Gallery, as an institution with which my professional connection is well known, and also in interfering between some of my most valued clients and the position I hold with them was quite unjustified. This course, together with the kind of methods adopted, constitute an unworthy departure from those right lines of professional courtesy and fairness which we claimed to uphold when forming our Society, but which Society has thus been used by the many as an organised instrument for harassing and injuring the professional practice of the one. The call for public competition, often fair and proper enough, has in this instance been raised with the knowledge that, after my many years of work and waiting for the development of this institution, for which I have done so much, both professionally and honorarily, such a call, if responded to, would be cruelly inequitable to me. In spite of my representations to the Society, made formally and at the right season, my words have been disregarded. The action against my interests has been persisted in, even though possibly tending in the long run (as I at first showed) to create antagonism between the clients aforesaid (viz. the Cardiff Corporation) and myself; and this, moreover, at a time of considerable importance in the history, architecturally, of that Corporation. That course, further, has laid disadvantages upon me to which I have referred when writing to the secretary of the Society. Nevertheless, although plenty of opportunity has existed for amending the position of

affairs during the weeks it has now existed, nothing of that kind has been done. Such action towards one who had been first president of the Society until a few days previous is too unmistakable in its intention to allow me to risk any mere affectation of good fellowship, and, much to my personal regret, I recognise the position created by the Society as prohibiting my joining in its meetings at present.—Yours very faithfully,

EDWIN SEWARD.

Mr. D. Jenkins, of Llandilo, writes to the editor of the *Western Mail*:—As one member of the Cardiff and South Wales Architects' Society, I regret the position the Society is now brought into by some Cardiff members who appear to act for all others in South Wales. If they cannot retreat from their contemptible attitude and disregard of professional etiquette after the emphatic protest Mr. Seward has made in his letter to the president, I cannot feel it any credit to remain one of them and shall soon act accordingly. As I do not live at Cardiff I can, without prejudice, look on both sides of this case. There is no doubt, to my mind, of the art gallery and the museum being in Mr. Seward's hands in a way which is honourable to him from the original competition, and from drawing up reports and plans for extending and utilising the new site. But these Cardiff members seem wishful to take advantage of the site being changed, and though knowing or having been told about the old plans, &c., try to tempt the committee by the cry for competition, in order to overthrow Mr. Seward for their own ends. It is nothing less than intrusion on individual rights for them to interfere and try to snatch a chance for themselves, to the injury of another man. Now, there can be no pretence or ignorance after Mr. Seward's clear and emphatic protest in writing to say that he has claims to the work. This ought to be sufficient from one of themselves, who had also just vacated the presidential chair, and would be so with every other society or institution, as we all earn our daily bread from work as to which we should not think of asking for pledges. As for architects raising such a question about one whom they well know has been engaged in the ordinary way, I do not remember such extraordinary petitioning and using of the names of members without their authority. I am sure the Royal Institute would condemn it. If I am wrong, let Mr. Vaughan, as president, submit or refer it to that Council for decision and satisfaction to all concerned.

THE PENN MUTUAL, PHILADELPHIA.

THE above woodcut represents the Penn Mutual Building, situated on the north side of Chestnut Street, between Ninth and Tenth Streets, Philadelphia. It was erected by the Penn Mutual Life Insurance Company, from the designs of Mr. Theophilus P. Chandler, jun., architect. The style is difficult to express by a single phrase, as must be the case with all progressive structures. It has a frontage of $77\frac{1}{2}$ feet, with a height of seven storeys, crowned by a double dormer attic and steep roof, making a total elevation from the sidewalk of 136 feet as regards the main part. But there is a wing, and that is carried up to the same height as the principal structure for seven storeys, but at that point a clock tower is superimposed upon it. The tower starts from the roof of the top-most storey, and not from the ground. The Post Office is set well back, and is thus given an amplitude of sidewalk; the next building west of Ninth Street has a little less sidewalk, but still some space is surrendered. Then comes the Penn Mutual, whose main body is on the line of that building, but the wing projects 12 feet and gains the level of the other buildings that commence at Tenth Street. These conditions would have permitted the erection of an actual tower, but that was not wanted. Hence the architect boldly made the tower an obvious supplementary construction, starting it from the roof of the wing and carrying it to a total elevation from the ground of 190 feet. The material used for the façade was Baltimore white marble, dressed but not polished, with a small amount of rock-faced ashlar used simply as a foil. The façade of the main entrance is arranged in three masses. Between the pillar and pier of the main entrance to the wing is a lintel supported by excellently carved corbels, and over this is a double pedestal forming the support for a marble statue of William Penn. The building is of fireproof construction.

WHITLEY-BY-THE-SEA, NORTHUMBERLAND.

THE popular seaside resort, Whitley-on-Sea, is being further developed. Plans have been passed by the local authorities for the whole of the sites commanding the main turnpike road from Whitley old village almost to the sea. The main road will be considerably widened, the houses will be self-contained, averaging about 19 feet frontage by 80 feet in depth, and will be known, when finished, as the Park Avenue. Some of the houses are almost finished, the remainder are in course of erection. They are pleasantly situated, commanding extensive country and sea views. They have neat elevations, and appear to have all the latest improvements, sanitary appliances and conveniences, and are sure to be an attraction to visitors and residents alike. It may be mentioned that the whole of the land has been recently purchased by the enterprising contractor, Mr. James Hilton, of Whitley, who has built largely in the neighbourhood, and with considerable success.

The plans have been prepared by Mr. A. Ross Hunter, architect, 131 and 133 Pilgrim Street, Newcastle-upon-Tyne. It would appear, however, that Whitley is not the only pleasure resort that is rapidly growing in the North, as Mr. A. Ross Hunter is just finishing four large stone houses at Warkworth with all the latest appliances and conveniences. Each house has an extensive garden at the front and rear; the fronts overlook the beautiful river Coquet and surrounding country, and the rear commands an uninterrupted view of the massive ancient and historical Warkworth Castle, belonging to the Duke of Northumberland, and which is free to visitors and is well worth a visit from any lover of antiquities. Morpeth, Alnmouth and Alnwick are in close proximity, and each have renowned histories. Mr. Hunter is also having finished some houses at Broomhaugh, Riding Mill (on the upper reaches of the river Tyne), one of the most charming spots in Northumberland, near to George Stephenson's birthplace, close to the Roman Wall and the ancient historical town of Hexham.

NOTES ON NOVELTIES.

Paradigm Skylights.—The excellent system known as the "Paradigm" skylight system has been recently invented by Mr. A. Edgumbe Rendle, a son of the late Mr. W. Edgumbe Rendle, of London, who was well known as a glass-roofing contractor and horticultural builder. For some years past Mr. Rendle has resided in America, being the owner of the "Rendle" skylight patents for that country, and soon after inventing the "Paradigm" skylight system, a company was formed in New York for the purpose of introducing the new system, and several important contracts have been secured, as follows:—New stations of the Brooklyn Bridge, New York and Brooklyn—45,000 feet super; Jacksonville Terminal Co.'s new station, Jacksonville, Florida—20,000 feet super; new station at Syracuse, New York, for the New York Central and Hudson River Railway—10,000 feet super; United States Government, Washington, Library of Congress Building; Chicago Edison Co., Chicago, skylights over power-house—15,000 feet super; Central Railway of New Jersey; Equitable Gas Light Co. of New York; Pencoyd Iron Works, Philadelphia, &c. The engineers of the New York and Brooklyn Bridge, Brooklyn, can speak as to the class of work done for them by the American Company; also the Chicago Edison Co., Chicago; Pencoyd Iron Works, Philadelphia, Pa.; Phoenix Iron Co., New York; Mr. Bernard R. Green, engineer, Library of Congress, Washington. Among the special advantages of the system are the following:—The main bar being made of rolled steel, greater strength is necessarily obtained than in sheet metal bars now being used all over the country. The steel channel bars are not exposed to the weather at all, being entirely and completely covered by the glass and "caps," and they can be kept painted and will last as long as the building. The "caps" are the only part of the patent "Paradigm" skylight system exposed to the weather, and as these can be made of strong copper, it will be readily conceded that a skylight or glass roof constructed on this system should outlast an ordinary skylight many years. It is the most economical skylight system by reason of the fact that we can supply it at a price that will almost compete with the ordinary sheet metal skylights. The cost of maintenance and repairs is reduced to a minimum. As the steel channel bar is so strong, averaging from $\frac{1}{8}$ to $\frac{1}{4}$ inch thick, a less number of roof purlins are required; for instance, purlins need not be less than 5 to 8 feet centres. Broken panes of glass can be replaced more easily and quickly than by any other method. The skylight bars are usually rolled in one length, up to 40 feet if necessary, so that defects through careless soldering and consequent leakage, as in the sheet metal bars, is an impossibility. The glass is all on a level and butted at joints; no ugly laps. The method of carrying off the condensation formed on the

under side of the glass is simply perfect. A skylight or glass roof glazed on the patent "Paradigm" system cannot get out of order. If no glass is accidentally broken there is no reason why the skylight should not last for a hundred years. For the roofs of greenhouses the "Paradigm" system of glass roofing

itself to engineers and architects. The cross bar is usually made of strong copper or other sheet metal. The glass rests on the edges of the channel bar, and should the iron contract or expand the glass is out of harm's way, so that if the metal contracted or expanded one-quarter of an inch (which, of

cannot be excelled. All the wooden sash-bars are done away with. The method used for making a watertight joint at the junction where two panes of glass meet, which permits the glass to be butted instead of being lapped, will commend

course, is unlikely), still the glass would be uninjured. The great trouble has been when glazing glass on iron (T bars being generally used), the breakage from the above cause has been enormous.

THE ARCHITECTURAL ASSOCIATION.

AT the meeting of the Association, Mr. E. W. Mountford, president, in the chair, the thanks of the members were passed to Sir A. Blomfield for affording them to visit the new Church House at Westminster.

Mr. H. H. STATHAM read a paper, of which we give the following abstract, on

The Bridges of London, Architecturally Considered.

In taking for my title "The Bridges of London, Architecturally Considered," I am aware that in the two last words I may seem to be begging a rather large question in assuming that there is an architectural quality in a bridge which can be considered apart from its utilitarian side. Some of us probably think, and I should be inclined to agree with them, that it is a great pity the professions of engineer and architect were ever separated at all; that every architect should be an engineer and every engineer an architect; and that the result of the separation has been that we have one set of men who devote themselves entirely to constructional problems, and ignore—are almost trained to ignore—the artistic and expressive aspect of construction, and another set who devote themselves mainly to the artistic side of construction and sometimes know much less of its scientific side than they ought to know. In regard to bridge building, however, there is a rather distinct line of demarcation in the work, and that is the line of the water-level. It must not be forgotten in considering the subject, that in building a bridge over water of any depth, and more especially water which is actuated either by strong currents or strong tides, the most difficult and in a sense the most

important part of the whole work is that which is under water, and it is impossible that this could be successfully dealt with by anyone who has not had special experience and special training in that kind of constructive problem. When we come above the water-line the problem becomes one of ordinary construction, which is, or ought to be as much within the province of the architect as the engineer, unless in such exceptional cases as that of the great lifting leaves at the Tower Bridge, which again form an exceptional problem demanding a kind of mechanical knowledge which is not properly within the domain of the architect.

We as architects may therefore rightly leave to the engineer the problem of bridge foundations under water, admitting our inability to deal with it adequately; we only claim to have something to say in the matter when the work gets above water. And this, not only because the constructional work there is not (or, shall we more prudently say, ought not to be?) beyond our capacity to deal with, but because the question of the design and expressive treatment of the superstructure, which comes into our special province, is of far more importance than it has been generally allowed to be. The fact is, there is hardly any kind of structure which may have greater influence, for good or bad on the architectural effect of a city than its bridges, in those cases where a large river flows through it. The bridges in such a case are among the most prominent objects in making or marring the general effect and impressions of the place. They are seen both from the banks and from the river; they are seen on both sides, unlike many town structures; they are seen from above and from below, from close at hand or from a distance. In the most crowded city there is a clear vista along the river and its banks. You see the bridges in succession, a perspective of beauty or a perspective of ugliness. And what class of structure can be more capable of beauty than a bridge? Its series of arches contrasting with the long lines of its cornice and balustrade, and with the masses of the piers; the cut-water bases of the piers, which every bridge built in running water must have, and which give such a special character of the picturesque founded on the practical; and, above all, its situation above the surface of water, with all its magical effect of movement, of glittering lights (even Thames water looks beautiful in the sunlight), or of calm reflections; can there be any greater possibility for the production of architectural charm than in such an erection, in such a situation? The very simplest stone arched bridge is an object of beauty if you trust only to its natural disposition of

HILL'S SLIDING-DOOR GEAR

lines and masses, and it takes a good deal of bad detail to thoroughly spoil it, unless the detail is very large and prominent indeed. Unhappily there seems to be now an increasing desire to build what are called "handsome" bridges, in which there is a great deal of detail, often very large and generally very bad; and I hope to show that some of the older bridges of London, now removed, which were much simpler in design than their successors, were also far superior in architectural quality.

Let us first, however, briefly consider the architectural treatment of bridges in a more general sense. In regard to architectural expression there are four principal points to be considered:—1. The shape and proportion of the arches; 2, the treatment of the soffit of the arch; 3, the treatment and design of the piers; and (4) that of the finish of the bridge along the top, *i.e.* the cornice (if any) and the balustrade or fence wall. This latter is entirely independent of the construction of the bridge, but its design may have an important effect on the general appearance of the structure.

For anything worth calling a monumental bridge in an architectural sense there is but one material, stone, which can be regarded with entire satisfaction from our point of view. There are cases, chiefly those of railway bridges, in which stone cannot be used, at all events for the portions between the piers; for ordinary traffic there is hardly any case, except that of a drawbridge, in which stone arches cannot be used as well and as satisfactorily as iron cantilevers or girders, as some of the existing examples among London bridges completely prove and with infinitely better effect. As soon as you introduce iron, however well-designed and however massive your stone piers may be, you at once destroy the monumental effect of the structure as well as its unity of expression; you force into architectural union two materials which are radically distinct in character and in properties; you introduce an element of decay, for however long iron may last, the most enthusiastic believers in that material can hardly pretend to believe that it will last as long as a built structure of granite or even of a good building stone; still worse, you introduce as a necessity the element of paint, a disagreeable artificially-made surface, which can never harmonise with nature as pure stonework will. For the finest effect attainable from a bridge it must be entirely of stone, balustrade and all; even an "ornamental" iron balustrade interferes with and spoils the breadth and unity of the composition.

The number and relative proportion of the arches is a

matter which is to some extent governed by practical considerations. Almost invariably it will be found that the older bridges have a larger number of arches of smaller span than the modern ones; in all the cases of London bridges which have been rebuilt, with the single exception of the Hammersmith Suspension, the modern ones have fewer and larger openings than those which they replace. It can hardly be questioned that the older type of stone bridge, with numerous and comparatively narrow arches, was in general a more picturesque object than the modern bridge with its wide spans and comparatively flat curves. Landscape painters who introduce a bridge as an incident in the scene will be found, I think, always to prefer a bridge of many arches to one of the modern type. But in the case of a river running through or past a great city, and which forms the water highway for its traffic, the reduction in the number of piers becomes a continually increasing necessity, which in the case of our last new bridge, placed at the point where the river traffic is thickest, has resulted in the employment of an entirely new mechanical arrangement for avoiding interference with the passage of shipping. Wherever water traffic has increased, however, there is always this continual fight going on between the architectural claims of the bridge and the practical claims of the water traffic. Some of the Thames bridges above the London district, such as Wallingford, Sonning and Chertsey, are very picturesque, and Kew is as charming a specimen of bridge architecture as could be seen; and as far as the two former are concerned there seems no reason why they should not remain as they are, since the traffic is not extensive except in the way of pleasure rowing-boats. But Chertsey Bridge, where there is more going on, and where the arches are unusually narrow, has been found to be a practical inconvenience, and being, as American visitors say of our cathedrals, "somewhat out of repair," it will probably be removed before long and will, undoubtedly, be replaced by one with wider spans—let us hope not an iron one. Kew I call a beautiful bridge, of finer design and much better built than Chertsey, and with fairly wide arches, and if it were an upper Thames bridge it might be adequate to its position for a long time to come. But it crosses the tidal portion of the river, where at spring tides the rush of water is tremendous, and it is at such times both an obstruction to the flow of water and a danger to the navigation. The fact of this necessity for the removal of some of our most picturesque existing bridges is an additional reason for calling attention to the subject of the architectural aspect of bridges.

The form of arch to be adopted must be to some extent ruled by the proportionate width of opening in regard to the height of the roadway above the water-line. In the old-fashioned bridges, with narrow openings, the semicircular or the pointed arch could be used, and there was little to choose between them except as a matter of consistency of style. Mediæval bridge-builders, however, were rather given to use a segmental pointed arch, with heavy longitudinal ribs or groins abutting against the piers, as in Old London Bridge and in the interesting old bridge at Huntingdon still remaining; but though this has a fine, solid and picturesque effect, it is bad practically, as it lowers the headway unnecessarily near the piers. For rather wider proportioned spans the Tudor four-centred arch would be a serviceable form if a pointed arch were desired as a matter of style, as it gives a flatter proportion, while at the same time rising quickly from the pier. When, however, we come to spans of 120 feet to 150 feet, as in Waterloo and London Bridges, none of these forms are applicable, and we have only the choice between an ellipse or a segment of a large circle, of which the first is illustrated in London Bridge, the second in Waterloo and New Putney Bridge. Of the two I think, on the whole, the ellipse is preferable. It is a complete curve instead of an incomplete one; it rises tangentially from the vertical face of the pier, which is more pleasing to the eye than the abrupt angle made by the segmental arch; and where the springing is not much above the water-line it has a practical advantage in giving more vertical space near the piers. For an arch of the same width and height, it of course means a rather flatter curve in the upper portion of the arch than would result from the use of the segmental arch, but the practical difference in this respect is not after all very great. The segmental arch is no doubt simpler to construct, and where a pretty good height can be obtained in proportion to the width, as in Waterloo Bridge (which is 37 feet rise to 120 feet span), there is something grand in the simple sweep of the segmental arch; but where the proportionate rise is less, as in Putney Bridge (which is 144 feet span to 18 feet 6 inches rise), the arches have an appearance of being jammed between the piers instead of "springing" from them, which is not agreeable to the eye.

The question of symmetrical spacing of the arches is one which has been often debated. Where there are any peculiar circumstances which afford a suggestion for a different treatment of different sections of a bridge, I think these should be taken into account and frankly expressed in the design. There is an interesting example of this in the old stone bridge over

the Dee at Chester, where the river is broken by shallows or rocks into several channels, and the bridge arches have been built of varying widths, just as the foundations of the piers could most economically be made; the effect is picturesque and characteristic. This is an exceptional case, however, and there can, I think, be no sort of excuse for irregular spacing of the arches of a bridge unless there is this kind of obvious reason for it in the nature of the site. But take the case, which may not infrequently happen, of a bridge over a river of which one side of the visible water area is shallow and unfit for navigation, and the navigation is necessarily confined to the deeper half of the stream; there would then be a legitimate leading to a picturesque treatment, building the bridge in a succession of narrow arches over the shallow portion (where the foundations of the piers would, if the ground were good, be a comparatively easy matter), and throwing one or two wide arches over the navigable portion. Thus there would be a highly picturesque effect of contrast produced, which would actually be a visible index to or proclamation of the physical conditions of the water-way. There are portions of the Thames where this reasoning in bridge-building would fully apply, but not within the London district. There we have no excuse, as far as the water-way is concerned, to depart from symmetry in design; and to my mind bridges which form portions of the architectural scenery of a great city should be treated symmetrically, when there is not any obvious practical reason to the contrary. But there is still the question whether we should preserve the same span in all the arches, or treat them with a symmetrical variation. Of our three finest bridges—London, Waterloo and Putney—the first and last are designed on the principle of keeping the central arch widest and diminishing the others in an equal ratio each way. In London Bridge the centre arch is 152.6 feet span, the two next 140 feet, the end arches 130 feet. In Putney Bridge the centre span is 144 feet, the two adjacent arches 129 feet, and the two end arches 112 feet. Waterloo Bridge, on the contrary, marches straight across the river with its regular stride of 120 feet to an arch. Which method should be employed depends partly on whether you are anxious to keep your bridge roadway perfectly level from end to end, in which case, of course, the unvaried width of arch renders it easier to do this, but in every other respect the merit seems entirely on the side of the symmetrical variation principle, with the widest arch in the centre. A slight rise towards the centre of a bridge does not seriously

MAURICE'S PORCELEINE,

For Painting and Preserving Wood, Stone, Metal, Plaster, or any Surface on which Paint can be applied.

BRIGHTER THAN ENAMEL. EASY TO APPLY. NO BRUSH MARKS.

Cheaper than Paint and Varnish where a glazed finish is required. A Saving in Labour, only two or three coats being required on new work.

SAMPLES FREE TO ARCHITECTS AND BUILDERS.

FOR WALLS AND WOODWORK.—Maurice's Porcelaine is the best article in the market when a bright and durable finish is required; it is easy to work and gives a lasting glaze equal to China.

CEILINGS.—Our White is incomparable, and will keep its colour for years; it has binding qualities that prevent Ceilings from Cracking.

ENGINEERING.—For Iron or Metal-work of all descriptions it is a protective against Corrosion, and gives a beautiful finish, and on account of its heat-resisting qualities is in every way suitable for Stoves, Engines, Electrical Apparatus, &c.

All the above remarks are Guaranteed, being the results of Practical Tests.

inconvenience the roadway traffic—indeed, there is a story of a country carrier who, on first crossing a modern-built bridge with a level roadway, grumbled that “he did not call that a bridge, for you could not tell when you came on it and when you were off it.” The slight curve of the balustrade and cornice line is more pleasing from a distance than a rigidly straight line; the variation in width of arch gives an increased interest to the design without destroying bi-lateral symmetry; while the greater width of the central arch is an actual convenience to the water-way traffic, especially on a river where a great deal of the barge traffic depends mainly on the tide for locomotion, and naturally keeps in the centre of the river where the tide runs strongest. The wide central arch is, in fact, only carrying out permanently and architecturally what had before been done temporarily, for the first step towards rendering some of the old London bridges more suitable for the increased water-way traffic consisted in knocking one or two piers out of the middle and making a wider arch there. That was done both with Old London Bridge and Old Putney Bridge, long before they were finally removed.

But the design of Waterloo Bridge suggests another point. I said just now that there was nothing in the condition of the water-way of the Thames at London to justify or suggest an unsymmetrical treatment of the bridges. But there is something to suggest this in the levels of its banks. The main line of traffic with which Waterloo Bridge is connected at its north end is at a much higher level than that at its south end. Perhaps few of those who, after alighting at Waterloo Station, are dragged by a straining cab-horse up the gradient leading to Waterloo Bridge, realise that this uphill tug is all in order that Waterloo Bridge might realise its uncompromising severity of design by being carried at a uniform level right across the river, from the high bank to the low one. In the case of London Bridge there is the same kind of discrepancy between the design of the bridge and the bank levels, but to a less degree, as the ground on the north side falls rather towards the bridge, and the difficulty has been partially evaded on the south side by “fudging” to some extent the lines both of the parapet and the roadway, so that about 3 feet of the necessary fall is obtained on the bridge itself, without the effect on the symmetrical character of the design being very noticeable unless looked for. Attention was drawn to this point in an interesting paper on the bridges of London, considered mainly from an engineering point of view, read four-and-twenty years ago before the Institute of Architects by

an engineer, Mr. Henry Carr. Speaking with special reference to Waterloo Bridge, he propounded the question whether the right treatment would not have been to have kept the highest point of the bridge as near as possible to its north end, and built it in a descending gradient from that point, to meet as far as was possible the lower road levels on the south side. There would then have been a long and easy gradient, partly on the bridge, instead of the present short and steep one up to the bridge level. Mr. Carr admitted, however, that “he would have been a very bold man who had ventured to adopt such a course;” and I think we must all agree that the majestic character of Waterloo Bridge would have been much impaired thereby. Still it is a question whether the architectural dignity of the bridge should or should not have been impaired for that practical consideration, a question which might perhaps enter into our discussion to-night.

In regard to the second point, the treatment of the soffit of the arch, this will depend somewhat on the general style of the design. In those bridges which are what is generally called Classic in architectural character, it seems almost a matter of course that the arch should be built with a plain flat soffit; and as there is no constructional advantage in doing otherwise, there is perhaps nothing to be said against this treatment when it is in harmony with the rest of the design. Certainly nothing in the way of ornament should be introduced on the underside of the arch, which is the constructive portion of the bridge, and should have an appearance of rock-like strength and stability. But if a bridge be designed with any of that more stern and sinewy character which we associate with Gothic work, the method frequently employed, as already observed, in Mediaeval bridges, of building the arch in parallel groins with a recessed surface between them, certainly gives additional force to the design, and may even be a saving in material, though such saving would no doubt be counterbalanced by the increased superficies of work on the groin ribs. This effect of parallel groins on the soffit has actually been adopted in some of the modern bridges with iron arches, the arches or cantilevers forming visible ribs, in a manner which is perfectly logical as an expression of the construction.

The pier of the bridge has been the great crux, in the architectural sense, of bridge designers, and it is where the modern bridge-builder most frequently fails, owing mainly to a departure from simplicity, a desire to do something clever and “handsome.” As before observed, a bridge must have a cut-water on the lower portion of its piers in the direction opposed

MESSRS. H. & J. HARDY,

ALBANY WORKSHOPS,

SWANAGE, DORSETSHIRE.

No. 2.—AUTOMATIC SELF-LOCKING ACTION.

No. 3.—THE SELF-HELP FASTENER.

A large number already in present use giving full satisfaction. Unrivalled.

WE beg to call your special attention to our Patent Combined Stay and Fastener, which, from its great advantages and easy mode of use, can well claim a superiority over the common kinds. You will notice that this Fastener has no complex system of working, is easy to fix, and, whether the casement is open or shut, does not project into the room, but hangs down the centre of the sash free from curtain or blind. The advantage of this Patent Fastener is that, being fixed in the centre of the sash, it affords protection against sudden gusts of wind when open, and keeps the sash safely closed when shut, as it acts as a fastener for the casement as well as a stay. Each of the three kinds of Fasteners affords the same advantages in all respects, as, though varying in shape, size, and price, are only different ideas of the same method. These Casement Fasteners can be used both for wood or iron, for single or double casements. The special pattern is used for fanlights to open outwards, and all can be used both for right or left hand. We can supply these Fasteners in any number of links, according to the extent the casement is required to be opened. We may also note that the Fasteners are well made and finished, can be had both in brass and iron, and are, therefore, well suited for any kind of residence. Quotations and further information will be given on application. Also testimonials. Please state in ordering whether you require them for single or for double casements.

Stay and Fastener shown in Action.

to the current; and in many old and simply designed country bridges the whole pier towards the current was built out at an angle, ending in a sharp point, and either carried up in this form to the parapet, forming a triangular "refuge," or stopped below the parapet by set-offs and becoming a triangular buttress. The down-stream side of the pier would be left flat. We must all have noticed such bridges in stone-building districts, and observed their picturesque effect. There are instances to be found, I think, among old bridges, and certainly among modern ones, where bridges in a running stream have been built with a cut-water both up and down stream—for symmetry, I suppose. It is better, no doubt, that the water should have a curve to run round uniting on the down-stream side of the pier, or it may wear away the angles, but it is quite sufficient for this purpose to make a semicircular finish to the plan of the pier on the down-stream side; there should be nothing like a cut-water, which should be confined to the up-stream side, otherwise you lose a natural source of character in the design. In the larger bridges which are erected over large rivers and in connection with large cities, the cut-water form is now seldom or never carried higher than is necessary to clear the highest water-level of flood or tide; to do more would be a serious waste of material in a bridge on a large scale. There is, however, a general sense that it is in the fitness of things that the pier should be emphasised by carrying its face beyond the face of the arch, both to divide the arcade in an architectural sense, and to give both the appearance and the reality of greater weight and mass to the pier. How is this emphasis to be expressed architecturally? In the Pont Neuf at Paris (a small bridge compared with our London ones) the treatment is very simple and very effective; the cut-water form is carried up to a considerable height and a semicircular balcony is corbelled out from it. The semicircle is a better form for an alcove or refuge than the triangular space which would be given by the shape of the pier itself; and the whole arrangement is both picturesque and practical, but it would not apply to bridges of such large scale as ours. There we have to leave the greater part of the cut-water as a bare shelf, bevelled or curved to allow any water that may get on it to run off, only the portion close up to the pier is generally treated as a square plinth to receive whatever kind of projection of the pier we may put on it. Now, constructively, this projection of the pier is, if anything, a buttress, for any constructive function that it can have is to increase the lateral stability of the pier, and it might quite suitably be treated as a buttress,

and sloped off to the main plane of the bridge. Most of our large modern bridges being, however, on Classic lines, the buttress would seem to be out of keeping as a matter of style, and in that case the simplest and most effective treatment is just to project the whole mass of the pier outward as a square projection, carrying the cornice round it. This is the way it is treated in London Bridge and Putney Bridge, and in some of the best of the larger up-river bridges—Kingston, for instance. But with too many of our modern bridge-builders there seems, unfortunately, to be a rooted idea that this projection of the pier is a place designed by Providence for the display of the columnar orders in some form or another. A couple of flat pilasters on the projection might give it a certain architectural grace without robbing the structure of its solidity, though certainly detracting from the appearance of power; but to put detached or semi-detached columns in place of the projection of solid masonry is to deprive the pier of the effect of mass, and to place a feature intended to support vertical weight in a position in which what you really want is lateral strength. And when, as we shall see in some instances, even the advantage of the graceful proportion and effect of the Classic column is abandoned, and short thick stumps are introduced, the result becomes palpably absurd as well as ugly.

The cornice of the bridge, if it is a bridge of Classic type, should range with the level of the roadway, representing the crown of the solid construction, so that the parapet can be designed equally for inside and outside appearance. The cornice should be of bold and simple character, as befits a grand engineering construction on a great scale; but on the other hand, we must guard against the mistake so often made in engineering works of seeking for "boldness" by means of mouldings of enormous size. The result of that is merely to make the work look coarse and to reduce its apparent scale. Engineers may no doubt shelter themselves behind the example of Michel Angelo, who did the same at St. Peter's; but that was one of Michel Angelo's mistakes. In regard to the parapet I think a bridge should always have a pierced parapet of some kind; a solid parapet gives it a heavy appearance, a pierced parapet offers a pleasing contrast with the heavy masses of masonry of the constructional portion, and at the same time marks the fact that it is an addition, and not an essential portion of the construction. But the more simple the design of the pierced portion the better; an exceedingly ornate parapet design is out of place, and seems to force itself on the attention too much, besides detracting from the

breadth and solidity of effect proper to a bridge. Unless a bridge has something decidedly Gothic in its general design, there is really nothing better for the position than a simple repeating baluster of the Italian type. The lamp standards should be placed over the piers, not in the centre of the arches. They are so in all the older bridges as far as I have observed; it seems to have become a modern practice to place them over the centre of the arch—a mistake both architecturally and practically. On the pier they assist in emphasising its vertical line, and seem in their proper place architecturally, and while the position makes no difference to the traffic on the bridge, it is certainly better for those in boats passing under the bridge to have a cross light from both sides of the arch than a single one over their heads.

It may be a question whether the spandrels of the arches should be regarded as a field for the introduction of ornament. I can only say for my own part that I can hardly imagine any kind of design for a monumental stone bridge which would not be spoiled and weakened in effect by cutting up the spandrel with ornament. In the case of bridges with iron cantilevers the space between the upper and lower member no doubt seems a suitable one for an ornamental filling, though the efforts that have been made in this direction have not so far conducted to the happiness of the spectators. Where there is a sufficient mass and projection in the piers it may be suitable enough to place a niche and a statue, provided that you are going to afford sculpture of the highest class and of a grand type of design.

The latter part of the paper Mr. Statham devoted to a detailed description of the history and constructional details of the London bridges, old and new.

Mr. W. D. CAROE proposed a vote of thanks to Mr. Statham for his paper, which was supported by Messrs. Halsey Ricardo, G. H. Fellowes Prynne, B. F. Fletcher, S. B. Beale, and passed by acclamation.

The paper was illustrated by lantern slides, and there was a good attendance of members.

In consequence of our not receiving a copy of Mr. Statham's paper in time, it was unavoidably left over. We have, however, much pleasure in giving the above extract of his very interesting paper.

THREE plans for a new covered market at York have been prepared by the city surveyor, and will be submitted at the next meeting of the Corporation.

UNINHABITABLE AND INSANITARY HOUSES.

A LECTURE on "Uninhabitable and Insanitary Houses: Some of the Causes, and a Remedy," was recently delivered by Mr. William Stevenson, house factor, Leith, before the Unionist Club. He said:—The subject of the paper I have to read to you is "Uninhabitable and Insanitary Houses." I propose first to point out what I consider some of the primary causes of houses becoming unhealthy; and second, I shall suggest what I think would be a successful remedy. You will naturally expect from the nature of my vocation that I have given this subject some consideration. The subject is one which could not be lightly passed over by anyone in the same occupation as myself. I have studied it in various ways and from many sides, and have arrived at conclusions and have formed opinions which I hope are in the main correct.

Before entering into the discussion of the subject, and putting before you my opinions and conclusions, I desire to mention at the beginning that this same subject of unhealthy houses has been recently discussed by two very eminent and learned gentlemen, each on different occasions and in different towns. At the Sanitary Congress, held in Glasgow in August last, Dr. Russell, medical officer of health for Glasgow, read a paper on "Uninhabitable Houses: Who inhabit them? Who own them? and What is to be done with them?" In that paper Dr. Russell laid the blame for unhealthy houses on the immoral compact entered into between the tenant and the landlord, and that this compact was leading landlords, factors, trustees, beneficiaries, bondholders and tenants down the broad road to perdition. On a more recent occasion, at Birmingham, this same question of unhealthy houses was made part of the groundwork and foundation of a great political speech by Mr. Chamberlain. He implied that houses became unhealthy because every man was not his own landlord. His words were, "I want to deal with the individual home. What is the best security and guarantee that the home of the working man shall be comfortable and shall be healthy? It is that a man shall be the owner of his own dwelling."

On a subsequent day at Durham he said that his proposal was put forward to elicit discussion and criticism. I have read the statements of both of these gentlemen as they appeared in the newspapers, but I have failed to find that either of them has studied the question to its foundation or traced the disease to the first cause, and thus neither has been able to put

forward a satisfactory specific for remedying the evil complained of.

I will now proceed to discuss the question as I understand it, and in doing so, it is to be understood that I am dealing more particularly with Scotland, and specially with Edinburgh and Leith, where I have the more practical knowledge. I have little practical acquaintance with English houses, and do not deal with them on their merits. Every man his own landlord and the owner of his own home is not a new cry and watchword, but a very old one indeed, and dating back for at least fifty years or more, and for the last forty-five to my own personal knowledge. It is an old story, and one which has been fostered and nursed by all kinds of building associations, loan societies and companies of a kindred kind. Edinburgh and Leith, where these societies have been sown broadcast, are peculiarly applicable as evidence of the success or non-success of the proposal "that the best security and guarantee that the home of the working-man shall be comfortable, and shall be healthy, is that every man shall be owner of his own dwelling." I question if any two towns can be found in the kingdom where, from the house of the ordinary working-man and artisan, up through the middle to the more wealthy classes, so large a proportion of houses is owned, and has been owned and occupied by their owners. The owning and occupying by their owners, of single houses in Edinburgh and Leith, is not a thing of yesterday but of generations back.

Within the last twenty or thirty years whole streets of new houses have been built in new and in suburban localities, suitable for occupation by the artisan, and by others higher in the social scale, and have been sold, to be so owned and so occupied by their owners. Houses of a less pretentious and imposing kind than the ordinary tenement have also been put up by building companies and by other builders, and with plots of ground, and have been disposed of to be occupied by their owners. The advertising pages of the newspapers afford indisputable evidence of the extent to which individual ownership of single houses prevails. The newspaper columns are filled with flats, half-flats and single houses for sale; but full and complete tenements, put into the market, are comparatively few indeed. It may be true—at least it cannot be gainsaid—that all these houses, when first built, were considered of the most perfect construction, and were supplied with the most modern sanitary appliances of the times. But do we find on inquiry and investigation that all these houses, which were

bought by their owners for their own homes, are still in a healthy, sanitary and comfortable state, according to present-day requirements? Is one-fourth of the houses built within the last fifteen or twenty years now in such a condition of repair and of sanitary convenience as will fully meet the requirements of tenants, and stand modern scientific tests and requirements? If I am right in my conclusions and in the statements which I put before you, then the proposition "That every man, the owner of his own home, makes healthy and comfortable houses" is a fallacy and a delusion, and will not bear investigation. This fact leads me to consider and inquire how it comes about that the houses which have been built, even at a very recent date, and which, when built, were constructed on the most approved plan, and fitted with sanitary appliances and other modern conveniences of the then most perfect kind, should in a very few short years become, so to speak, unhealthy. In house property we have a commodity of human construction, capable of almost indefinite increase; but a commodity, immediately on completion, subject to decay and deterioration, and from the very first requiring constant care and attention to keep it in repair and order. If we exclude premises owned and held for manufacturing and mercantile purposes, and confine our inquiries specially to house property, I think it will be found that comparatively little is held in ownership by the upper or wealthy classes, but that it is held by the lower or less wealthy classes, not for speculation, but as a sure and safe investment, and held by persons who have acquired the means they are possessed of by care and frugality, and who have invested the whole or nearly so of their means in property as a competency for old age for themselves and wives, and with the expected reversion to their families or relatives after their death. In the investing of their carefully-gathered means little account has been taken of, and no provision has been made for, the continual outlay required for the repairs and upkeep which is necessary on house property. If money has been borrowed on bond or mortgage, as is often the case, the strain on the resources of the holding to make all ends meet is excessive. Every penny possible requires to be exacted from the rents by the owner or the life-renter. Not more than what is absolutely compulsory is expended either on repairs or improvements. The better class of tenants gradually remove to houses of more recent construction, and where they find the more modern appliances and conveniences. The houses have to be let to a class of more undesirable tenants, and gradually the property gets into disrepair, and from bad to worse goes down the hill

till ultimately, when it reaches the beneficiary, it is scarcely worth having.

In the case of tenement or other blocks of building owned by a separate individual, for every separate house, and having many rights in common, repairs cannot be easily executed, except under compulsion of the authorities, and then only of the barest needs, and at a cost out of all proportion to the amount of work done. All this, perhaps, from the want of means by some or want of inclination by others of the common owners. If one owner desires improvement of his holding or the introduction of some more modern convenience or sanitary appliance, he is handicapped in his attempt to effect it, except at an inconvenience and cost disproportionate to the value of the alteration wanted. There is little or no control over the introduction of undesirable neighbours, and by the introduction of such persons the neighbourhood becomes deteriorated. The dissatisfied leave the place, and either sell their house at a loss or let it at what rent can be got and to such tenants as they can command. And so this neighbourhood also gradually goes down the hill and becomes an undesirable locality. Owners of single houses and property in common are handicapped at every corner against keeping their holdings in a good and healthy condition and repair by the disregard, carelessness, or impecuniosity of their neighbouring owners. Many owners of their own houses, and who are sensible of the insanitary and uncomfortable condition of their dwellings, continue on from year to year to occupy them, well knowing and hiding their defects because of inability to meet the outlay, or perhaps a want of desire to effect the improvement, and it is only after the property is put into the market for let or for sale that the defects are found out.

In all large trading or manufacturing concerns managed on true business principles a certain portion of the profits are yearly set aside to meet depreciation, and for repairs and renewals. This is specially the case with our most successful shipping companies. I have never yet found any such thing as a reserve fund of this kind with individual owners of house property. Herein lies a pertinent cause of uninhabitable and insanitary dwellings. I have pointed out how liable house property is to decay and to deterioration. But hitherto it has been held as if it were an investment practically incapable of decay or deterioration, and as if after having been once built it were incapable of improvement, and had no necessity for any reserve funds for effecting these objects—in short, held on rule of thumb, and on no business or commercial principle what-

ever, and no provision or calculation made for decay. Building and other loan societies, and the easy facilities with which loans can be got on mortgage over house property, are much to blame for bringing into the field of ownership large numbers of impecunious persons, and who have not the wherewithal to hold on business and commercial principles the property they have acquired, and to maintain it in that state of repair and health which is required, even when they have the desire and knowledge to do so. Many persons become owners of their own houses and of property who have never counted the cost on any sound business system.

There are most certainly, and it would be a pity if it were not so, very many individual owners of house property who hold their property as an investment, and who during their own lifetime and with their own sanction, have the greatest care and concern that their properties should be always kept in the highest and most perfect state of substantial repair. But the life of every person is an uncertain commodity, and when that passes away, then comes other rules and other modes of management.

The leaving of property in life-rent has hitherto been a fruitful cause of rapidly leading property to decay and ruin. A life-renter has no interest in many cases in maintaining the property in any better repair than is sufficient to take as much out of the holding as possible. Needful repairs are executed with a grudge. Any substantial improvement which would retain a good class of tenants is absolutely refused. One by one the good tenants remove, and their place is bit by bit refilled by a lower and still lower class of tenants. The property itself not only goes to decay, but the neighbourhood and neighbouring properties become deteriorated past recovery at the same time.

The carelessness and indifference of tenants, and not infrequently wilful destruction by them of property, is becoming more and more every year a burning question, and one which will in the near future have to be sternly faced. The destruction from carelessness and indifference is not confined to the lower class of tenants, but is a cause of complaint against many of the would-be upper class, and whose standing and position lead to an expectation of better things.

Neighbouring owners, I have said, and as I have good reason to know, are often the cause of the deterioration of a neighbourhood. Thoughtless and regardless modes of management lead to serious loss to other owners who have the best intentions.

DOWSON, TAYLOR & CO., LTD. LONDON: 14 Victoria St., S.W.
MANCHESTER: Blackfriars Bridge. And at GLASGOW and PARIS.

Trustees holding for beneficiaries and heritable creditors in possession have hitherto been seriously handicapped in keeping and maintaining property in a good and lettable condition, and abreast of modern improved requirements. They had power only to do necessary repairs. When mortgages had been foreclosed it was a certainty that the free income from property had been insufficient to meet the interest. In such cases it was almost hopeless to expect improvements or any repairs beyond that allowed by law. The buildings may have been good and substantial so far, but by the inability of the holders to introduce from time to time better and more modern conveniences it is found impossible to retain the best class of tenants. They migrate to where these modern conveniences are found. The Heritable Securities Act, just become law, will substantially improve the position of heritable creditors in possession.

The speculative and the jerry-builder is the back on which is most often laid the blame for unhealthy and insanitary houses. The speculative builder is not an article of self-creation. He was brought into existence to meet the demand for a cheap and flimsy article. He is not to be blamed for providing the article wanted by impecunious buyers, greedy of big interest and big bargains, and who have neither the knowledge nor the desire to appreciate a good and substantial article—the best value in the end. He is the counterpart of the Cheap Jack, and owners of the slop-shops on the bridges and elsewhere, and who supply the demands for the cheapest clothing and other articles. Even Mr. Chamberlain in his speech at Birmingham stated that he had been in search of a Cheap Jack, and had found one who could supply the very best article in the market in the way of healthy houses for working-men at 140/ each.

In the preceding remarks, if you will allow me shortly to recapitulate, I have pointed out that the owning of their own homes by the occupiers have not been successful in making healthy and comfortable houses, but, on the contrary, has specially contributed in Edinburgh and Leith in making houses unhealthy and insanitary. I have pointed out that the system of leaving property on life-rent is another of the causes which contributes to the same end. I have shown that the holding of property by bondholders and by trustees assisted to the same end. I have also shown that even the individual owner of property having the best intentions, and because of neighbouring owners and the uncertainty of his own existence, and because of the inability to control what may come after him, is unable to prevent the very best class of property from becoming

unhealthy, and I pointed out that a serious factor in the question is the universal want of any reserve fund on which to rely for effecting repairs and renewals. These and the want of a perpetual and continuous system of management, continuing on from year to year in perpetuity and without a break, all lead to the same end. Experience has thus taught us in the past, and the reports of medical officers of health and sanitary inspectors tell us in the present, that individual ownership of house property has been unable and unsuccessful in its management in preventing property becoming the slums and the rookeries of our towns.

I now come to the second part of my story and the more pertinent point—the remedy which I would apply. If my indictment against the holding of property privately or by individual owners is found to be relevant, and if the proof which I have set before you brings in a true bill, as I hold it does, then I submit that all individual and private ownership in house property in towns should cease and terminate. I make the recommendation advisedly, unreservedly, and in its broadest sense to all house property having common rights. In the owning of property for letting purposes I would exclude the State; I would exclude municipal authorities and every other elected body elected by the ratepayers for administrative purposes only. The constitution of all such bodies unfits them for the management of commercial and mercantile undertakings.

I would like to see, and I recommend that the owning of house property be taken up by joint-stock companies, or such like corporations, or by some kind of syndicate, and which might be limited and might be co-operative. In the formation of such companies and corporations there could be no risk if judiciously gone about. The property would be managed from year to year on uniform and business principles, and with perpetual succession in the management—uniform, continuous, not erratic, spasmodic and uncertain. The dividends would be paid half-year and half-year, uniform and of known quantity, with sufficient reserve for all emergencies or improvements and for renewals. I see no reason why working men of all classes should not join in and invest their frugal savings in such a manner from the single one pound and upwards. Such investments would not be speculative—expected to yield from 6 to 10 per cent.—but I see no reason why a uniform and constant dividend of 4 to 4½ per cent. should not be made. In such companies owning whole and undivided blocks of houses, and having no mutual obligations, improvements in internal arrangements and fittings, and the introduction from time to time

157 STRAND, W.C. (Four Doors from Somerset House), LONDON.

of the most modern and approved sanitary appliances, could be done with perfect facility and freedom, as it was found that such became necessary and advantageous for maintaining the houses in the best and most forward condition; and by always keeping the houses in such forward condition, retaining and keeping the best class of tenants, and by keeping a good class of tenants, maintaining the locality also in a high-class position. In such companies or corporations shareholders and members could with every confidence bequeath the life-rent to one person and the fee in reversion to others, knowing that the life-renter would have no control in deteriorating the principal, and that the fee would go down to the reversionaries unimpaired, and in the same substantial condition in which it was left at the date of bequest.

The model after which I suggest construction is the insurance companies and the Scottish bank. Intelligent and energetic artisans would be of the utmost use in the management. Their training in various trades connected with property would make them so. And if we are to believe in the success of the co-operative enterprise and benefit societies, it is manifest that they have business capacity.

I have been unable to find out the existence of any kind of company or association in Scotland of the nature or constitution I recommend, except one in Glasgow—The Glasgow Workman's Dwellings Company, Limited. It has been in existence for a short time only, and on June 30 last they issued their first full year's statement of accounts. Through the courtesy of their secretary I have been furnished with a copy of that report and with other documents relating to the company. The paid-up capital is nearly 15,000*l*. After paying all expenses for the year, one-third of the preliminary expenses in forming the company, a dividend of $3\frac{1}{2}$ per cent. was paid. 198*l*. was placed to a reserve fund, and 36*l*. was carried forward to next year. The company's operations consist chiefly in buying up old and insanitary property, and, after putting it into a perfect state, letting it out. The rents are all weekly, and from 2*s*. to 3*s*. This company is perhaps of a semi-charitable nature, but it is substantial proof of what can be done with even the lowest class of property, and with the poorest but decent labouring classes. It is providing them with good and healthy houses, and it is paying the shareholders of the company an honest dividend.

It has been decided to light the choir and nave of Bristol Cathedral by electricity.

EXTRAVAGANCE IN COUNTY COUNCIL VALUATIONS.

THE following important letter to Mr. Boulnois, M.P., from Sir Peter Edlin, Q.C., who, as chairman of the London Quarter Sessions, is better acquainted with the subject than any expert, reveals how enormous is the waste of money every year in consequence of the unscientific procedure adopted for the "valuation" of property in the Metropolis by the County Council:—

"64 Queensborough Terrace, W. : February 23, 1895.

"Dear Mr. Boulnois,—I duly received your note of yesterday, and need scarcely say that I followed its lines with much interest. I am naturally reluctant to refer to the subject-matter—in short, for reasons that will appear, it is repugnant to me; but there have been so many and such gross and persistent misrepresentations publicly made with regard to the appeals brought by the London County Council to the Court of Quarter Sessions against the totals of the valuations of several of the London parishes and unions, that it is desirable, from every point of view, that the actual and more material facts should be known and correctly appreciated, and more especially so by those whom, like your constituents, they so seriously affected.

"These appeals, twelve in number, were instituted after the last quinquennial valuation for the purpose of raising the totals of gross and rateable values as they had been settled by the assessment committees respectively after appeals to special sessions, the ulterior object of the Council, and doubtless the actuating motive, being to increase the sums upon which the county rate would be leviable, and thus enable them to levy a larger amount without raising the nominal rate; or possibly to reduce the nominal rate, for of course the larger the aggregate total of the Metropolitan assessments the smaller need be the rate in the pound requisite to meet the Council's expenditure.

"It may appear incredible, but it is a fact nevertheless, that in these twelve appeals the Council presented no less than 38,307 impeachments of separate valuations, relating to as many distinct hereditaments, alleging that in respect of each of them the assessments of gross and rateable value were too low. In no case did they complain of any assessment being too high. Even if the objections for under-valuation were well founded, the injustice of this exclusive and partial selection could not escape notice. In some instances the increase demanded in rateable value did not exceed 5*l*., and it was admitted that, although the 'totals' were raised, the actual valuations of the

individual hereditaments would remain unaltered. Now it is obvious that each of these impeachments presented separate issues, and had it been possible for the Court to try them they would have sufficed to occupy it day by day for a dozen years or more. In short, these appeals, irrespective of their being based upon an entire misconception of the law and of legal right, were absolutely and manifestly impracticable. Let it be observed, by the way, and pardon me if I interpose the remark, that they constituted a portion of the work which the Council imposed upon the judge of the Court, to whom they were at the same time refusing to accord a proper salary.

"In saying that these voluminous appeals were brought upon an utterly erroneous view of the law, and of the legal rights of the Council under the Metropolis Valuation Act, 1869, I convey, as concisely as may be, the opinion expressed in the respective judgments of the Master of the Rolls and the Lords Justices of Appeal, as well as by the House of Lords, in the St. George's Union case (*vide* Law Reports, 1893, 2 Q.B., 476, and House of Lords, Appeal Cases, 1894, p. 600).

"But—as I have been repeatedly asked—what has to be said with regard to the costs to the community of these useless and abortive law suits? Here certainly we have a question of interest to every ratepayer. The Council itself refuses to disclose the actual figures—as you observe, members have been unable to elicit them from the responsible officials; but I am informed by those who have carefully followed all the legal and other proceedings that the total cost to the metropolitan county of these appeals cannot possibly have been less than 50,000*l.* Indeed, a gentleman professionally connected with one of the respondent unions has publicly stated that the total expenditure upon them will amount to not less than 75,000*l.* I assert unhesitatingly that for any eventually useful public purpose whatsoever, as many English sovereigns drawn from the pockets of the ratepayers might just as well have been thrown into the Atlantic Ocean. There will probably be some inquiry relative to this matter in Parliament, but the more widely the facts and circumstances are known the more correctly will metropolitan ratepayers appraise the claims upon their gratitude of the promoters of these extensive and expensive lawsuits.

"The prolonged litigation foreshadowed in these appeals when notice of them was first given, and the enormous expenditure on both sides that would inevitably attend the prosecution of them, might well alarm the local authorities, and before there had been any judicial expression of opinion with regard to the

law applicable the respondents in seven of them came to terms with their opponents, orders by consent being made by the Court; but, except in two cases, no order as to the costs of the appeal. Of these seven, therefore, I will say no more than that the costs to the parties respectively must have amounted to a very considerable sum.

"But as to three of the other appeals the results have been disastrous. In the parish of St. Marylebone the Council impugned 3,610 of the assessments upon the ground of undervaluation, each of these enumerated objections, as pointed out, raising distinct issues. I gave twenty-seven days to the hearing of this one appeal, and again and again I drew the attention of the learned counsel appearing for the appellants to the inevitable futility of the proceedings—be the opinion of the Superior Court upon the fundamental legal question underlying the case what it might; and again and again I deprecated further expenditure of money upon it. I would refer to contemporaneous records in proof of this—*vide The Times* (Law Report) for Monday, November 28, 1892, and for Tuesday, December 13, 1892. It appears from the former report that it was calculated that if the Court were required to determine each of the three thousand and more issues raised in this suit the folio volumes in which the shorthand notes of the proceedings were daily transcribed would stand one upon another 11 feet high. But protests, warnings and remonstrances were in vain; be the consequences what they might, the Council were determined to go on. Not until the Lords Justices had delivered their judgment upon the prohibition rule in the St. George's case would the County Council desist from the further prosecution of their appeal against the St. Marylebone totals. Then, of course, the abandonment of it became imperative, and the appeal was dismissed, but the Court of Quarter Sessions was not asked to make any order as to the costs on either side. It appears that the costs to the parish only of this appeal were 6,900*l.*, but the total expenditure of the Council upon it must have very considerably exceeded that sum. The figures given at a recent meeting of the Council—5,773*l.*—would be of only partial application, inasmuch as when the appeal was first proposed, and before it could be actually brought, a preliminary fee of 3,000 guineas was paid to their surveyor, and fees of 500*l.* to each of his three assistants. Added to which the establishment charges, consequent on the requisite augmentation of the staffs in the solicitor's and surveyors' departments for preparing and collating the voluminous schedules and other documents, must have been very heavy.

No. 26.

HALLIDAY'S CLAPTON LIGHTS.

Simple, Powerful, Economical. Reflection and no Complication.

OPEN TOP, AS SHOWN, OR VENTILATING. PLAIN OR ORNAMENTAL.

Much used in Places of Worship, Lecture Halls, Board Schools, Shops, Large Offices, Markets, &c.

Suitable for wherever a Very Powerful, Well Diffused, Soft, Economical, and Easily Managed Gas Light is desirable. Made in Five Sizes.

HONoured WITH SUNDRY IMITATIONS.

Seven years from Invention up to April 1890 over 11,300 sent out. But

Up to the end of 1893, over 23,000 sent out.

A PERPLEXED GAS INSPECTOR.

"There has been so great a reduction in our consumption of gas at Speke Hall, Battersea, since we had your CLAPTON LIGHTS, that the Gas Company declared our meter must be out of order. They have had it examined, and can find nothing wrong.

R. H., London, September, 1893."

The Gas Light also at this Hall is said to be over twice what it was before.

Free by post, carefully packed inside patent roller, on application to the Publisher,
P. A. Gilbert Wood, 175 Strand, W.C.

"Passing from St. Marylebone we come to the St. George's Union case, in which the respondents obtained the rule for a prohibition. Notwithstanding the unanimous judgments of the Master of the Rolls and the Lords Justices, the Council appealed therefrom to the House of Lords, and with the like result—again their appeal was dismissed, and they were ordered to pay all the respondent's costs, including, of course, those incurred in each of the Courts below. The total amount of the money expended in the persistent prosecution of this hopeless appeal may never be precisely ascertained, but it can scarcely have been less, it was probably more, than what was thrown away in the St. Marylebone case. The chairman of the Local Government and Taxation Committee admitted, at the meeting of the Council on the 29th ult., an expenditure by the Council on this appeal of 3,998*l.*, to which have to be added the costs of the respondents, which had not then been taxed, but which have since been ascertained to amount to 8,000*l.*

"There is enough for reflection in what is above stated, but there still remains for mention the reckonings in the City of London appeal. This also, in view of the judgment of the House of Lords, had, of course, to be abandoned by the Council. There was a justifiable item in it in consequence of arithmetical errors, but as to the substantial issues presented it was on all fours with the other suits, no less than 1,107 valuations being impugned, including those of a hundred or more of the principal hereditaments in the City; and as must be apparent, the costs incurred in instituting this proceeding and in resisting it must have been very large indeed. It was, of course, ultimately dismissed, though for the reason above stated, with cross-orders as to the costs on balance much to the disadvantage of the appellants.

"There should be no concealments with regard to the matters dealt with here. The Council's surveyor, who received the fee above mentioned for furnishing materials in the St. Marylebone case, was doubtless one of an expert staff similarly remunerated for the like purpose in the other metropolitan parishes or unions; and if the entire cost to the metropolis—the bills of the respective respondents as well as of the appealing Council—could be approximately computed, and the sum total presented to the public eye, the obligations of the electors and ratepayers to those who, in the exercise of a brief authority, thus persistently wasted public money in speculative litigation and abortive lawsuits, would be properly appreciated.

"Be it borne in mind, too, that although in some instances the parishes may have been recouped for the costs incurred in

defending their position, each will nevertheless have to contribute to the rate levied for the Council's disbursements.

"I am desirous, as far as possible, of dissociating my individual part and action as chairman of the County Sessions in respect of these matters from the grave public interests involved; but my relation to the County Council is unfortunately notorious, and it is with some satisfaction that I point to the Law Reports in refutation of the falsehood insinuated, that the Court of Quarter Sessions did not from the first take the same view with regard to the untenable position assumed by the Council in these suits as was afterwards expressed by the highest legal authorities.

"I remain very truly yours,

"P. H. EDLIN.

"Mr. Edmund Boulnois, M.P., &c."

NOTTINGHAM MASTER BUILDERS' ASSOCIATION.

MEMBERS of the Nottingham Master Builders' Association assembled in large numbers at the Lion Hotel, Clumber Street, on the occasion of the annual dinner of the Association. In the unavoidable absence through indisposition of the president (Mr. Enoch Hind), the chair was occupied by Mr. George Fish. The vice-president (Mr. James Wright) filled the vice-chair, and those present included Messrs. J. J. Adams, T. Barlow, A. G. Bell, T. Cuthbert, Dennett & Williamson, Gilbert & Gabbittass, Gell & Son, A. Hinsley, W. Hall, L. Lloyd, G. A. Pillatt, A. Priestley, R. Simpson, J. Shaw, J. W. Woodsend, Buxton & Attewell, C. Taylor, J. H. Vickers, W. Maule, Dennett & Ingle, John Walker & A. Brown, and J. Whitehouse (Derby Master Builders' Association) and F. Atkin (secretary). Letters of apology for inability to be present were read from Messrs. Enoch Hind, G. J. Brownell, H. Vickers, R. Bulley (Birmingham) and J. Cooper.

The Chairman submitted the loyal toasts, which having been duly honoured, the Chairman proposed "Success to the Master Builders' Association," remarking that he was sure the members all regretted the absence, and the cause of that absence, of their president, Mr. Enoch Hind. In proposing success to the Association, he thought he might say that the builders in Nottingham had been very much "out in the cold" for a long time, but there now seemed to be a prospect of better weather and also plenty of work in the town. He must tell them that what had been done during the past year had not been all that

J. ATTWOOD.

STOURBRIDGE.

The only Attwood in the Trade.

could be desired. When he addressed them on the occasion of the last annual dinner he said they were desirous of establishing a uniform code of working hours. So far that had not been brought about, but he hoped that during Mr. Hind's tenure of office they would be able to accomplish it, so that all trades might commence work and finish at uniform hours. The financial condition of the Association, he was pleased to say, was very flourishing. They had gone to considerable trouble in working out a schedule of prices during the past year, and they were hoping that a deputation from the Association would shortly meet the architects in the town on that subject. There was no doubt that such a schedule of prices as had been compiled would prove of great benefit to the master builders of the Association. A deputation of the Association had met the borough engineer in regard to matters relating to drainage, and it was purposed to meet the works and ways committee and the engineer with respect to the by-laws of the town. Further than that, the Association had had before them several important matters bearing upon the building trade, and it behoved the members to hold together and to give every support to their President during the ensuing year. He was pleased to say that the greatest good feeling existed between the masters and workmen in the building trade in the town, and also between the master builders and the local architects, and it seemed to him there was every prospect of success for the Association and the building trade.

Mr. J. W. Woodsend responded. It was, he said, but a natural desire on the part of that Association to endeavour to improve their trade and the conditions under which they worked. It was a matter for congratulation to know that the Association was in such a sound financial condition, and also to hear from the chairman the good work which had been done by the various deputations during the year. As a member of those deputations he could bear testimony to the kindness and courtesy with which they had been received by the borough engineer, and he felt sure that the architects in the town were quite in accord with the objects of the Association. He believed they felt it was a right thing for the builders to combine together, and that they would assist the Association as far as they possibly could. It was only a laudable desire on the part of the master builders to so improve the trade as to insure for them a balance on the right side at the end of the year. He wished to emphasise the fact that the architects and the borough engineer had treated them with courtesy, and that so far they had worked in perfect harmony with them. The

Association would shortly approach the architects with regard to the schedule of prices, and he felt sure they would do what they could for them. When he first became connected with the Association they experienced considerable difficulty in getting builders to join, but he was proud to say their membership was now something like fifty. In Mr. Hind they had a man of great energy and ability, and he believed the Association had every chance of a successful career.

Mr. James Wright proposed "The Town and Trade of Nottingham," remarking that though the builders had gone through a period of depression in trade, there were encouraging signs of an improvement in the near future.

Mr. Woodsend responded, and said the Corporation had done very much to improve the town during the last thirty years. With regard to the depression in trade which they had had to deplore for so long, he was fully convinced that one of the most formidable forces which the trade and commerce of this country had to contend with was the paid agitator. With the genuine working man he had every sympathy, but he was sure that the agitator was more responsible for the bad trade than anything else.

Mr. Williamson proposed "The Visitors," to which Mr. Walker responded.

LIGHT AND AIR CASE.

AN appeal was heard in the Court of Appeal, *Wasson v. Pawson & Leafs, Limited*, against a decision of Mr. Justice North in the action brought by Messrs. Wasson & Fawell, of St. Paul's Churchyard, against Messrs. Pawson & Leafs, Limited, of the same place. As we reported lately, the plaintiffs claimed an injunction to restrain the defendants from erecting and raising their new building in Dean's Court, Doctors' Commons, so as to darken, injure or obstruct any of the ancient lights passing to the plaintiffs' premises, and also from permitting to remain any building already erected which shall cause any obstruction to the said ancient lights. The plaintiffs also claimed damages. A motion was now made on behalf of the plaintiffs for an interlocutory injunction until the trial of the action or further order, in the terms of the first part of the plaintiffs' writ, excluding the mandatory part. The defendants' premises are very extensive, comprising a number of houses in St. Paul's Churchyard and some in Carter Lane. The defendants have recently

The Manager,

BUILDING TRADES EXHIBITION, 222 STRAND, W.C.

obtained from the Ecclesiastical Commissioners a new lease of a portion of their premises, on the terms (*inter alia*) of rebuilding that portion, and in so doing they propose to raise their new buildings to a considerably greater height than the old ones. By this alteration the plaintiffs allege that the access of light to their premises will be seriously obstructed. The defendants, on the other hand, deny that any material injury will be inflicted upon the plaintiffs. The new buildings have been commenced. There was a great conflict in the evidence, as is usual in cases of this kind. The plaintiffs' most serious complaint was that the defendants' new buildings would obstruct the access of sunlight to a small office or room, 10 feet by 7, which had been used for years as a room for sampling and examining cloth, for which it was said sunlight was absolutely necessary. The defendants were proposing to set back their buildings 10 feet, but to raise them from 44 feet to 84 feet. Mr. Justice North granted an injunction until the trial of the action or further order, though he was by no means certain that the plaintiffs would succeed at the trial. But, on the balance of convenience and inconvenience, he thought the better course was to grant the interlocutory injunction. He required the plaintiffs to give the usual undertaking as to damages. The defendants appealed.

The Court dismissed the appeal.

Lord Justice Lindley was of opinion that Mr. Justice North had arrived at a proper conclusion. With great respect, however, he thought the learned judge had understated the amount of obstruction of light to the room or office in question. His lordship would not stop to comment on the difference of opinion between the professional witnesses; but what struck him very forcibly was the evidence that the light in this room was actually diminished now, although the defendants' building had only been carried up at present 15 feet. That was a piece of clear and tangible evidence, and it stood absolutely uncontradicted; the light in this room was by no means what it was before. The room, though small, was an important one, being used for examining and sampling cloth. It was satisfactory to feel that, in affirming Mr. Justice North's decision, this Court was not giving weight to any mere fanciful injury. It was said that the learned judge had attached too much importance to the balance of convenience and inconvenience; but his lordship thought that, if the evidence at the trial stood as it now stood, the reasonable probability was that the plaintiffs would obtain their injunction. Then it was said that the injunction would cause very great inconvenience to the defendants. No doubt it

would. But they could go on with part of the building up to the old height, and there they must stop. In his lordship's opinion the plaintiffs had made out a *prima facie* case—a strong *prima facie* case—and the proper course was to dismiss the appeal with costs. It was obvious that there was a good deal behind, and his lordship hoped that the parties would come to some amicable arrangement.

Lord Justice A. L. Smith delivered judgment to the same effect.

PATENTS.

[This List of Patents is compiled specially for this Journal by Mr. G. H. Rayner, of the firm of Rayner & Co., Consulting Patent Agents, 37 Chancery Lane, London, W.C., from whom all particulars and information relating to Patents may be had gratuitously.]

APPLICATIONS FOR PATENTS.

- 2949. John Bell Irving, for "Improvements in or relating to 'lobster back' chimney cowls."
- 2958. John Brides and George Walter Conchie, for "Improvements in sliding window-sashes and frames."
- 3044. Moses James Adams, for "Improvements in appliances for connecting and distributing the water-supply to sanitary and other appliances, and taking the waste therefrom."
- 3069. Harold Lyon Thompson Lyon, for "Improvements in locks."
- 3114. John Henry Cuttler, for "An improvement for securing window or sash-cords to window-sheets."
- 3159. Eugen Rittmeyer, for "Improvements in door-locks."
- 3177. Walter Thomas Christian, for "Improvements in window-sash and like fastenings."
- 3189. James Curtin, for "Improvements in ventilation apparatus."
- 3192. Frederic Cooke, for "Improvements in or relating to the disinfecting of water-closets, drains and other places."

PURE WARM AIR AS SUPPLIED TO

Truro Cathedral; Londonderry Cathedral; Sherborne Abbey; Kilmore Cathedral; Stanley Cathedral, Falkland Islands; Cardiff Catholic Cathedral; the Queen's School Chapel, Eton; Cork Asylum; Leicester Asylum; and to upwards of three thousand Places of Worship; and a great number of Mansions, Houses, Hotels, Hospitals, Schools, Warehouses, Factories, Workhouses; Cork Law Courts, &c., &c.

Sir WILLIAM BROADBENT encloses cheque for the "GRUNDY" HEATING APPARATUS supplied to his house, and is glad to say that it has proved very satisfactory for warming and ventilating as required. The principle of the apparatus is most excellent. To Mr. Grundy.

84 Brook Street, Grosvenor Square, W.: December 8, 1893.

PROFESSOR TYNDALL writes:—

October 24, 1893: Hind Head House, Haslemere.

Dear Sir,—My house being so well provided with grates and flues for the generation and distribution of pure warm air, I have been thus enabled to spend my winters in England instead of on a foreign shore.—Yours very truly,

JOHN TYNDALL.

Fever Hospital and House of Recovery, Cork Street, Dublin: October 26, 1894.

Dear Sir,—I have much pleasure in informing you that we have found your HEATING APPARATUS a great success in our new Epidemic Hospital, which consists of a two-storey building, each storey containing two large wards, a smaller isolation ward, and two nurses' rooms. It is easily managed, does not cost much for fuel, and the air entering is most pleasant, warm, and free from smell. It is with the full concurrence of the Managing Committee I give you this testimonial. Yours faithfully, JOHN MARSHALL DAY, Registrar and Resident Medical Officer.

NEW READING CASE.

To Librarians of the Public Libraries and Reading-rooms.—A new handsome Reading Case can be supplied at a nominal charge of 2s., by post 2s 6d., on early application to the Publisher, 175 Strand, W.C.

SPECIAL NOTICE TO THE TRADE AND OTHERS.

[Extract from a lecture on Architects' Libraries by Professor T. Roger Smith, F.R.I.B.A., at University College, October 10, 1893.]

"Lastly, let me recommend the back volumes of the professional journals. In the course of years all sorts of architectural topics come up in the public press and before the professional societies, and if you hunt through the indexes of these publications when you are seeking for information which eludes you in books, you will often be rewarded."

There has been a considerable demand for the back numbers of *The Architect* during the last three or four months, which we have no doubt has arisen from the remarks made by Professor Roger Smith, as contained in the above quotation; but the consequence has been that our stock of back numbers is getting very low, and consequently, in future, the charge for back numbers of previous date to January 12, 1894, will be 6d. each.

A few of the back volumes may still be had, price 12s. each.

NOTICE TO ALL WHOM IT MAY CONCERN.

MESSRS. W. & R. LEGGOTT, of Silens Works, Bradford, Yorkshire, and 226 High Holborn, London, W.C., have the sole right of making, manufacturing, or constructing Fanlight and Skylight Openers, known in the Trade as "Silens," or "Leggott's Openers," under their various Patents, all of which are unexpired and unimpeached and of full authority and effect.

The word "Silens" is cast on all their Silens Openers.

Any person who may be found infringing such Patents or making Fanlight or Skylight Openers protected by such Patents, or any of them, or selling or otherwise dealing in the same, will be proceeded against as may be advised.

TRADE NOTES.

ADDITIONS having lately been made to the Greenock Academy (Messrs. H. & D. Barclay, Glasgow, architects), the "Climax" continuous exhaust ventilators have been used for the ventilation, and have been supplied by Messrs. Cousland & Mackay, the sole manufacturers, Glasgow.

WE learn that Messrs. E. H. Shorland & Brother, of Manchester, have just supplied some more of their patent Manchester grates to the new Board Schools, Barrow-in-Furness.

IN a note announcing the change of address of Mr. H. T. Owens to 81 Smallbrook Street, Birmingham, we are informed that the special patterns of locks, brassfoundry, &c, as shown

in his catalogues, have been purchased by Messrs. Alfred Brown & Co., lock manufacturers and brassfounders, 81 Smallbrook Street, Birmingham, and therefore all goods specified are to be transferred to them. All orders entrusted to them will receive careful and prompt attention. Messrs. Alfred Brown & Co. keep a large stock of ironmongery of a thoroughly reliable quality, and orders can be supplied quickly.

AT the monthly meeting of the Middlesbrough School Board, the recommendation of the building committee that the tender of Messrs. Bastiman Bros., amounting to 3,732l. 2s., should be accepted for the additions to Denmark Street School, was referred back for consideration. It was decided to obtain a suitable site for a new school, to accommodate 1,300 children, in the district south of the railway and east of Boundary Road.

IT is reported that since the recent severe weather no fewer than 12,230 lead pipes have burst in Liverpool. The consumption of water, owing to taps being left running, has been enormous, the quantity being 57,000,000 gallons in excess of that used in the corresponding period of last year.

IN allusion to the lift accident at Lloyd's, which, unhappily, was fatal in one case, we would call the attention of the public to the fact that Messrs. Easton, Anderson & Goolden, Limited, engineers, London and Erith, have a patented safety attachment that can be applied to any system of hydraulic lift, and which will obviate any accident that might happen through the bursting of any of the pipes, besides preventing the speed of the lift from ever exceeding the given maximum.

THE *Glasgow Herald* says:—On account of the unwillingness of the original offerers for the digger, mason and brickwork to guarantee the completion of the buildings for the fever hospital at Ruchill within the period of two years, the health committee have resolved to recommend the acceptance of the offer of Messrs. Morrison & Mason, Limited, to do the work, that firm guaranteeing the completion of the hospital within the period stated. The original offer amounted to 101,616l. 14s. 5d., and Messrs. Morrison & Mason's, which was the second lowest, is about 1,101l. higher.

WE have been requested to announce that Mr. Waller, the manager of the Self-Lock Roofing Tile Co., has just been round all the principal towns, with the result that a great number of tiles have been specified by architects, and in many places agencies have been appointed for the sale of tiles and the hiring of machines.

MILTON ABBEY CHURCH, NEAR BLANDFORD.

VARIETIES.

SOME Manchester capitalists have formed a limited company, called the West Rhyl Land and Building Company, with a capital of 20,000*l.*, for purchasing the Rhyl Winter Gardens and the adjoining lands from the executors of the late Rev. Charles Whitaker. This, together with the new marine lake, will develop the west end of the town in a remarkable degree. A syndicate of Manchester gentlemen have purchased a quantity of land on the Morwylfa estate at Rhyl, on which it is intended to erect a magnificent hydropathic establishment, fitted with every modern convenience. Messrs. Darbyshire & Smith, of Manchester, are the architects, and the contract has been let to Messrs. W. Brown & Sons, of Salford.

AN inquiry has been held at the Town Hall, Yarmouth, relating to the application of the Town Council for sanction to loans amounting to 5,550*l.*, distributed as follows:—For flood prevention, 3,800*l.*; for construction of new road, 800*l.*; latrines on the South Denes, 500*l.*; and public walks and pleasure-grounds, 450*l.*

THE report of the committee of management of the Surveyors and Auctioneers' Clerks' Provident Association states that continued progress has been made during the year ending December 31, 1894. The membership on December 31, 1894, was 142, against 82 at the end of 1889. There has been no special call on the benevolent fund, and while the sick fund receipts have increased the payments have decreased, and the balance to the credit of the fund has increased by 20 per cent. On the life assurance fund there has been no claim since the Association was started. Seven new policies were issued during the year 1894, assuring the sum of 460*l.* The annual general meeting of the members and subscribers was held at the Auction Mart on Wednesday.

THE tender of Mr. Williams, of Sleaford, has been accepted for the construction of waterworks at Hickington, for the Sleaford Rural District Council.

AT the meeting of the Leeds Corporation, it was proposed that a grant of 10,000*l.*, the estimated cost of making alterations and providing additional tank accommodation for dealing with the sewage at Knostrop, should be made.

THE Bolton Town Council have decided to purchase Rhodes Farm, Clifton, the property of the Earl of Derby, at 200*l.* per acre, for the purposes of their sewage treatment scheme. It is estimated that the scheme will involve an expenditure of 75,000*l.*

THE sessional meeting of the Sanitary Institute will be held at the Parkes Museum on Wednesday, March 13, at 8 P.M., when a discussion will be opened on "Back-to-Back Houses," by Mr. James Niven, M.B., M.A., medical officer of health, Manchester, with illustrations of various types of back-to-back houses met with in practice, and the methods adopted for dealing with this class of property by Mr. Thomas de Courcy Meade, city surveyor, Manchester.

WE understand that Mr. H. A. Henderson, F.S.I., auctioneer and surveyor, 70 Finsbury Pavement, E.C., has just concluded the sale of a freehold ground-rent of 1,500*l.* per annum, secured by high-class residential flats at South Kensington, facing the Gardens, for the sum of 37,500*l.*

A VERY striking success has, we hear, attended the issue of Messrs. Cassell & Co.'s new serial, "Battles of the Nineteenth Century." Two large editions were sold within four days of publication, and a third edition has been produced.

A DOUBLE number of "The Paris Mode" is published this week, the price being the same as for the ordinary issue, viz. one penny. The editor makes in this number an offer, under specified conditions, of wedding-dresses to those who receive an offer of marriage whilst wearing a dress made from designs appearing in "The Paris Mode." This journal now offers its readers free patterns cut to measurement, free insurance and ree wedding-dresses.

THE *Scotsman* says:—The tenacity of the frost is causing a good deal of difficulty to the Edinburgh water authorities. The city is not in the enjoyment of anything like its normal supply of water, and a staff of no fewer than eighty men is even yet engaged each day in serving out water by means of upstand pipes, water-carts, &c., in the localities where the supply has been frozen up. An enormous amount of damage has been done to the service pipes of the Water Trust. The number of 4-inch pipes that have been burst by the frozen

water within them is simply without end. In some instances the supply pipe for half a street or terrace has had to be taken up. It has been found that the frost has penetrated the earth to the depth of about 3 feet.

THE *Daily News* Paris correspondent says that the Western Railway Company has presented to the Town Council of that city a scheme for railway communication between the Courcelles girdle station and the exhibition of 1900. It proposes to double the present girdle line between Courcelles and the Trocadéro, where the exhibition railway would branch off, going through Passy and across the Seine by Moulineaux to the Champ-de-Mars. The terminal station there would be greatly enlarged. The estimated cost is 920,000*l*.

WITH a view to induce the construction of a better style of shops and fronts, the directors of the Confectioners and Bakers' Annual Exhibition, which is to be held at the Royal Agricultural Hall, Islington, have decided to give 220*l*. in prizes for specimen shops to be fitted at the hall during the next exhibition, from September 21 to 28.

In the estimates of the Office of Works is included a sum of 1,000*l*. for the partial renewing of the heating apparatus in the palm house, Kew Gardens. The total length of hot-water pipes in the palm house has been estimated at 22,600 feet, or about 4 $\frac{1}{2}$ miles. Notwithstanding, it has always been difficult to maintain a satisfactory temperature in the north wing during winter.

AT the monthly meeting of the Leeds Association of Engineers Mr. Alfred Towler read a paper on "Corliss Valve Gears." The increasing demand for cheap power for manufacturing purposes, the generation of electricity, &c., had again, he said, brought the Corliss engine to the front.

AT the meeting of the Glasgow Association of Students of the Institution of Civil Engineers, Mr. John M. M. Munro, Assoc.M.Inst.C.E., read a paper on "Electric Tramways and District Railways." Commencing with some general remarks on the electrical transmission of energy, he described the application of electricity to the working of tramways and district railways. An interesting account was given of the Carstairs Electric Railway, a short private light railway over a mile and a quarter long, with a gauge of 30 inches, and light permanent way for passenger and general estate traffic between Carstairs Railway Station and Carstairs House, the power being generated by utilising the falls of Cleghorn, and transmitted by rails forming a low fence on each side of the line.

THE Harrogate Town Council have received sanction from the Local Government Board to borrow 5,100*l*. for the purchase of the Crescent estate. Plans have been prepared for laying the estate out as a public recreation-ground.

AT the meeting of the Midland Institute Engineering Society, Birmingham, a paper was read by Mr. Edward C. R. Marks on "Lifting Machinery." After references to several ancient appliances for raising and lowering heavy bodies, particulars were given of modern examples of hand-power lifting machines, including a description of Young's mechanism for automatically sustaining a suspended load. Mr. Marks illustrated typical types of hydraulic lifts and described the system adopted in the construction of inclined or cliff railways.

AT the special meeting of the general committee of the City Improvement Trust of Glasgow it was resolved to have plans prepared with a view to the probable erection of one or more blocks of buildings with houses of one apartment at rents from 4*l*. to 5*l*. and of two apartments at rents from 7*l*. to 8*l*.

THE *Irish Times* says an extensive seam of coal has been reached at the new Dungannon Collieries, at a depth of about 190 yards. Several tons were raised and tested for steam and domestic purposes, and proved to be of excellent quality, and much superior to Scotch coal.

THE Port sanitary and hospital committee of the Liverpool Corporation have received notice of sanction to borrow 26,000*l*. for the extension of the City Hospital North.

THE Birmingham City Council have authorised the technical school committee to expend 14,000*l*. on fitting up the new school in Suffolk Street.

AT the meeting of the Denton Urban Council it was announced that the Scott family intended to present the Lads' Club building and its contents, the engine-room and electrical plant, three cottages in Queen Street, and a plot of land adjoining the Lads' Club, containing an area of about 1,330 square yards to the town. The land was to provide accommodation for the proposed technical school, and toward the cost of this building the family being willing to contribute the sum of 800*l*. The gift in all amounts to about 6,760*l*.

AT the annual meeting of the subscribers to Paisley Infirmary, it was stated that a sum of between 50,000*l*. and 60,000*l*. had been subscribed for the new infirmary buildings.

THE Athens correspondent of the *Standard* says Herr Durm, the German architect, has left on his return to Berlin. His report on the preservation of ancient monuments in Athens

has been submitted to the Ministry. In it he advises that immediate steps should be taken for the restoration of the rear portion of the Parthenon, and that four raised aqueducts should be constructed to carry off rain water. In regard to the Erechtheum, he recommends the replacement of fallen stones as nearly as possible in their former position. Other classical buildings, in Herr Durm's opinion, do not need to be restored. The Archæological Society of Athens will undertake the necessary works without appealing to the liberality of foreign nations.

THE Theatre Royal at Glasgow has been completely destroyed by fire, and the damage is estimated at about 30,000*l*. A previous Theatre Royal on the same site was burnt down seventeen years ago. The directors have resolved to proceed at once with the rebuilding of the theatre, and they hope to have it open before the end of this year.

A GENERAL meeting of the Sun Life Insurance Society (the seventh under the new constitution and the eighty-sixth since the establishment of the Society) will be held at the chief office, No. 63 Threadneedle Street, on Wednesday, April 3, at 2 P.M., for the purpose of considering the accounts of the Society for the year ending December 31, 1894, to receive the report of the managers and to elect an auditor.

NOTES ON NOVELTIES.

Concealed Casement Stay.—The patent Concealed Casement Stay (Hewitt's patent) is an admirable appliance for use with casements opening either inwards or outwards, and it has the advantage of locking automatically either when closed or open at any angle. Being out of sight anything in the way of unsightly apparatus is absent. Among other advantages it may be of interest to note that for sashes opening outwards the hook supplies a want in furnishing a "pull to." For full length casements opening inwards there is no unsightly projection or sill to trip over. Also, forming part of the sash it can be painted in accordance with the sash, and thereby is always neat and clean, the architectural lines of the casement being also preserved unbroken. There is a distinct merit in regard of the automatic action, which renders the stay particularly desirable and suitable where there are children, as also in many cases being fixed to sashes beyond their reach. Messrs. Nettlefold & Sons, of 45 High Holborn, who supply the patent concealed

casement stay, will be pleased to supply all particulars concerning the same. Their illustrated catalogue of general and builders' ironmongery, containing over 160 pages, will be referred to at length in a subsequent issue.

Sewer-Pipe Joints.—Messrs. J. & M. Craig, of Kilmarnock, are bringing out a new pipe, the rights of which they have purchased from the patentee, Mr. T. Fitzgerald. A most satisfactory test has lately taken place in Dublin in the premises of Messrs. Monsell, Mitchell & Co., 67 to 73 Townsend Street. The method of joining sewer-pipes exemplified in the new invention has been devised to overcome defects in the old system, which resulted not only in considerable trouble and expense to builders, but in many cases involved imperfect drainage and consequent liability on the part of householders to typhoid fever and other dangerous maladies. Messrs. Craig & Co., Kilmarnock, who are now manufacturing pipes with the new joints, have appointed Messrs. Monsell, Mitchell & Co. their sole agents for them in Dublin. The new joints, by an ingenious arrangement, insure in the connected pipes that perfect uniformity of bore which is essential for proper drainage, and the efforts to attain which have hitherto invariably given such trouble to engineers, contractors and others. In addition to this they save a considerable amount of labour, enable the fitting of "gaskin" to be dispensed with and require less than half the amount of cement that is necessary to join pipes in the ordinary way. Mr. D. Baird applied a hydraulic pressure of 100 lbs. to the square inch to the joints without discovering the slightest sign of leakage, and several architects, engineers and contractors examined the joints, and expressed themselves as being pleased beyond all expectations.

CHURCH BUILDING SOCIETY.

THE Incorporated Society for Promoting the Enlargement, Building and Repairing of Churches and Chapels held its usual monthly meeting on February 21, at the Society's house, 7 Dean's Yard, Westminster, the Rev. Canon C. F. Norman in the chair. Grants of money were made in aid of the following objects, viz.:—Building new churches at Barnsley St. Peter, Yorks, 30*l*.; Ellistown in the parishes of Ibstock and Hugglescote, Leicester, 60*l*.; Great Saughall All Saints, in the parish of Shotwick, near Chester, 50*l*.; and Skelmanthorpe, in the parish of Scissett, near Huddersfield, 45*l*. CITY PRINTING WORKS.

THE fine new printing works of the Geraldine Press, Limited, 21 Whitefriars Street, Fleet Street, E.C., and also the block of offices belonging to *Answers*, Limited, 24 Tudor Street, E.C., formerly lighted by gas, are now lighted throughout by electricity. Mr. E. R. Dolby, Assoc.M.Inst.C.E., of 8 Princes Street, Westminster, acted as consulting engineer for the proprietors. The current is produced in the basement of the works of the Geraldine Press, Limited, by a compound-wound direct-current dynamo, built by Messrs. Crompton & Co, and driven direct by an engine made by Messrs. Belliss & Co., of Birmingham. About 195 lamps have been installed in the works, and about eighty lamps in Tudor Street, and the lighting of both premises is controlled from one switchboard fixed close to the dynamo. The large Hoe machine used for printing *Answers*, and also the Marinoni machines used for printing the large number of other papers published at the same offices are lighted up internally by incandescent lamps which much facilitate work. The wiring of the buildings was carried out by the Electrical and General Engineering Co., of 86 Leadenhall Street, E.C., under the supervision of the consulting engineer.

TESTING MATERIALS.

A LECTURE was delivered by Mr. A. S. E. Ackermann at the meeting of the Civil and Mechanical Engineers Society on "Testing Machines and the Testing of Materials." The lecturer entered fully into the principles governing many of the various

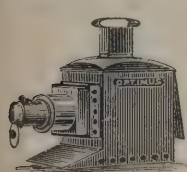

and well-known testing machines, and pointed out the good qualities, faults and difficulties of working with them. Various methods of gripping and holding the specimens to be operated upon were described. This was followed by details being given of the proper method of shaping the specimens, and of measuring and recording the results obtained, and the instruments used for this purpose, particular attention being drawn to several extensometers, particularly those of Professor Unwin. Explanation was given of certain laws that it was well those making tests should bear in mind in working out results. The lecture was illustrated by samples of metals and woods that had been tested; these were kindly lent by the authorities of the City and Guilds of London Institute and Mr. E. H. G. Brewster, who lent samples of steel boiler plates that had been tested by him in connection with boilers of his design. The peculiarities exhibited by some of the metals were very marked, and were prominently brought to the notice of those present. The necessity for testing materials was fully brought out in a discussion which took place towards the close of the meeting, at the invitation of the lecturer.

PUBLIC WORKS IN THE CITY.

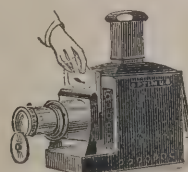

THE engineer to the City Commission of Sewers, Mr. D. J. Ross, has presented to that body a report on the works executed in his department last year. He states that 387 houses were drained and 127 dangerous structures reported upon and completed. The frontages of a number of houses in various streets were set back with a view to widening the thoroughfares. The whole of the premises on the south side of St. Paul's Churchyard, lying between Dean's Court and Paul's Chain and extending back to Carter Lane, being about to be rebuilt, lines of frontage were arranged. Dean's Court was to be widened from 10 feet to 22 feet. Memorials were sent to the Commission urging the completion of the widening of Lower Thames Street and the approaches to Billingsgate Market. Plans were prepared showing the properties required to be taken between St. Paul's Station and Tower Hill to make the thoroughfare 35 feet and 40 feet wide respectively. These were submitted to the London County Council, who agreed to contribute one-third of the net cost of the improvement at the west end of Upper Thames Street provided the Commission would undertake the portion of the proposed northern approach to the

"OPTIMUS" MAGIC LANTERNS SUITED FOR DRAWING ROOM AND LECTURE HALL.

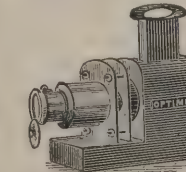

Each Magic Lantern is efficient for exhibitions. The Lens gives crisp definition, being a superior Achromatic Photographic Combination with rack and pinion. It is fitted to a telescopic lengthening tube, so gaining increased focal accommodation. The Condenser is composed of two plano-convex lens of 4 inches diameter. The refulgent lamp has 3 wicks, yielding a brilliantly illuminated picture. Each is complete in box. Pairs for dissolving arranged in one Box at same prices. Lever Disolter, 8s. 9d.

Tower Bridge within the City, towards the cost of which portion the County Council were prepared to contribute one-half. The question of making an improvement at the western end of Cheapside had also, with three alternative lines, been submitted to the County Council, but no result had yet been arrived at. The widening of Milton Street had been abandoned, the compensation demanded being excessive. Negotiations were in progress for widening the entrance to Wood Street from Cheapside. The number of defective gas-lights observed during the year was 113. The full contract quantity of gas had been given generally throughout the City and the regulators kept in proper condition. Both the gas-lamps and the electric lights were used during the six days of fog in the year. The electric lighting of the City was continued throughout the year. There were now 483 arc lamps in use. The total length of main thoroughfares lighted by arc lamps was about 13 miles. The number of gas-lamps discontinued was 1,338. The cost of water for flushing streets, sewers, &c, had been 3,261/. The street cleansing had gone on as hitherto. No fewer than 1,186,000 people and 92,000 vehicles entered the City daily, and 301,000 persons passed the entire day at work within the City—numbers which were not equalled, or even approached, by any other city in the world. The quantity of refuse removed had been 72,782 van loads, or about 233 per day. The usual arrangements had been made to meet the emergency of a heavy fall of snow. The number of interments during the year at the City Cemetery at Ilford was 4,875. All the rooms and shops at the artisans' dwellings, Petticoat Square, had been let, and the artesian well furnished an ample and continuous supply of water.

ELECTRIC EXPLOSIONS.

THE following letter has been addressed by the Board of Trade to the Chairman of the electric-lighting committee of the St. Pancras Vestry:—

Board of Trade (Railway Department), 7 Whitehall Gardens, London, S.W.: February 28, 1895.

Sir,—Adverting to the interview which you were good enough to give me yesterday, and to the conversation which we had on the subject, I am directed by the Board of Trade to state, for the information of the electric-lighting committee of the St. Pancras Vestry, that Major Cardew, the electrical adviser of this Department, has discovered, in his investiga-

tions into the recent explosions in the street boxes used for electrical supply in St. Pancras, that a remarkable deposit on some of the insulators contained a considerable quantity of the metal sodium.

The presence of this metal, which is highly inflammable by contact with water, appears to be so grave a source of danger and to afford so reasonable an explanation, in connection with the accumulation of escaped coal gas, of the several explosions which have recently occurred, that it devolves upon the Board of Trade, without any delay whatever, to investigate the causes of the deposit of this substance, with a view to its prevention, and in this investigation they have asked for the assistance of the Royal Society and of the Institution of Electrical Engineers.

In the meantime, in order to prevent as far as possible the recurrence of similar explosions, the Board of Trade would strongly urge that the vestry, through their electrical committee, should immediately:—

1. Provide a thorough system of ventilation for their conduits and street boxes.

2. Reduce as far as possible the space in their street boxes within which an accumulation of gas can occur.

3. Make a thorough inspection of their mains, and remove the above-mentioned deposit wherever it is found to exist.

As regards the means to be taken for prevention of the recurrence of such deposit, the Board of Trade hope to be able to communicate with you further without delay.—I am, &c.,

COURTENAY BOYLE.

The following reply was sent to the Board of Trade:—

Electricity and Public Lighting Department, St. Pancras Vestry Hall, London, N.W.: March 1, 1895.

Sir,—A special meeting of the electricity committee was held last evening, when the Chairman reported the conference held at your offices on Wednesday last on the subject of the recent explosions, and your letter of the 28th ult. was considered.

I was instructed to inform you that the committee desire to record appreciation of the courtesy shown by you in the desire to assist the vestry, and are thoroughly in accord with the Board of Trade in their desire to prevent a recurrence of the explosions that have recently taken place.

With regard to the several recommendations contained in your letter, the committee have instructed their engineer to have fixed, without delay, ventilating pipes for getting rid of

any accumulation of gas in the manholes and culverts; and, pending further consideration respecting reducing the size of the manholes, to fill them up as far as practicable with bricks. Extra men have also been engaged inspecting the mains and removing whatever deposit may be found on them.

The committee note the Board of Trade have asked the Royal Society and Institution of Electrical Engineers to investigate into the causes of the deposit of the metal sodium, and that the Board will inform the vestry of the result of such investigation.

The committee also expressed a hope that the Board of Trade would bring pressure to bear on the gas company to remedy the defective state of gas mains and services in this district, and thus remove the primary cause of the explosions.—
I am, &c., A. E. PYCRAFT.

Sir Courtenay Boyle, Board of Trade.

THE CARDIFF IMBROGLIO.

THE following additional correspondence has passed between Mr. Seward and Mr. Bruce-Vaughan respecting the museum:—

Queen's Chambers, Cardiff:

March 1, 1895.

My dear Vaughan,—Your reply to my letter is only a repetition of the inconsistent suggestion that I should discuss my business affairs with gentlemen who are concerned in an attempt to deprive me of an honourably-acquired engagement. The incident which first disclosed this attempt was my being pressed to sign a certain requisition, already signed by a majority of Cardiff architects, to the purport of which the names of many others were afterwards attached without their sanction or knowledge. This requisition (it was urged) was merely intended to raise the question of the borough engineer's connection with architects' work, but I paused long enough to discover that the document not only made no reference whatever to that gentleman or his work, but that it related solely to the museum building, which I was perfectly well known to be connected with as architect. In the present instance I will pause again—sufficiently to await the issue of that just and right consideration which the authorities will certainly extend towards one who has acted diligently for them in respect to the Cardiff Museum and Art Gallery. I can now, however, appropriately quote from my letter to our honorary secretary, sent for presentation five weeks ago at

your "architects' memorial" meeting, but not read there, viz. —"I hope, for the credit of the local profession, that this matter will be dealt with very judiciously. It contains opportunities for displaying ill-will of a small kind, as well as some possibilities for permanent and unprofitable discord. But it can also call out a proper spirit of fairness and justice." It could—but did not. I alluded last week to my business being harassed. This was no mere figure of speech. For some time past individual acts of very unprofessional interference between myself and clients, whose confidence had been earned, have been forced on my attention. These, when taken together with the present action, convince me that the Cardiff Architects' Society is not the body of men to redress them. Finally, any discussion of details of the museum matter must, as far as I am concerned, remain with the parties rightly affected, viz. the authorities and myself—Yours very faithfully,

(Signed)

EDWIN SEWARD.

E. M. Bruce-Vaughan, Esq., Cardiff.

Cardiff: March 2, 1895.

My dear Seward,—I was very much surprised this evening to see the letter I received from you yesterday printed in this evening's *Express*, and the more so because I had not even replied to it. But you appear to me to be too anxious to give publicity to what I consider at this moment a purely personal matter, and of little or no public interest. The letter which I received on the 21st inst. (the day of our annual dinner) was also in the hands of the press before I had replied to it, and as no one had read that letter but myself it was quite clear to me that you had given copies of it to the press, and sent their representatives to interview me on this subject. In your letter of January 21 last, and again in this letter of the 1st inst., you make what amount to two distinct and grave charges against our Society, which if proved would stamp the conduct of those present at the memorial meeting as dishonourable and unprofessional. First, you say "that we have influenced the authorities to such an extent as to cause you to be deprived of the position of architect to the Cardiff Museum and Art Gallery;" and again, that the method we have adopted constitutes an unworthy departure from those right lines of professional courtesy and fairness which we claimed to uphold when forming our Society. But what are the facts? It came to the knowledge of some of the members of the Society that it was the intention of the museum committee to advise the Corporation to advertise for designs in competition for the proposed new museum and art gallery on the Park Place site, and a requisition was

sent to the hon. secretary requesting him to convene a special meeting to consider the advisability of limiting the competition to architects practising in the county borough of Cardiff. At this meeting your letter of January 21 was read by me, and the points of importance in it, which I quote—"the museum work is in my hands"—"I have grounds for a strong legal claim, which will be held to if the Corporation should be induced to ultimately deal unfairly with me"—were emphasised by me as strongly as possible. But, on the other hand, it transpired that there was a desire in the minds of some of the members of the museum committee to advertise this work in competition, and Mr. Edwin Corbett read the following letter from the vice-chairman of this committee:—

38 Charles Street: January 24, 1895.

Dear Corbett,—The museum building committee was only appointed last week, and, so far, has not even been called together, much less appointed an architect; they cannot, therefore, be pledged to anyone. My own opinion is that plans will be advertised for in the usual way.—Yours very truly,

C. T. VACHELL.

It appeared quite clear from this letter and other information which was given to the meeting and to myself personally that several members of this committee were firm in their opinion that you had no claim, legal or moral, to the position of architect to the proposed building in Park Place, and that it was the intention of the committee to advertise, to use the vice-chairman's expression, for plans in the usual way. With these facts before us, Mr. Edwin Corbett proposed and Mr. C. B. Fowler seconded the following resolution:—"That the Cardiff, South Wales and Monmouthshire Architects' Society memorialise the Cardiff Museum committee to the following effect:—That unless they have already pledged themselves to any architect, they should invite a public competition for designs for the new museum buildings proposed to be erected in Park Place, the competition to be under the rules of the Royal Institute of British Architects." An amendment was proposed by Mr. G. E. Halliday and seconded by Mr. H. Budgeon, to the same effect, but suggesting that the competition be confined to Cardiff architects, but the resolution was carried. It was also proposed by Mr. Chotton James and seconded by Mr. E. H. Bruton, that the printed list of members be sent with the resolution. The printed list not having been corrected for the year, a type-written list was sent with the memorial to the town clerk. An account of this meeting, with the names of the members who composed it, appeared in the papers the next morning.

This appears to me to be a fair statement of our conduct as a Society in this matter, and the very head and front of our offending hath this extent—no more; and don't you think that some people may consider that, to quote your own words, "you have departed from the right lines of professional courtesy and fairness which we claimed to uphold when forming our Society?" And for these reasons:—Your refusal to give us the grounds of your claim to the position of architect to the proposed building in Park Place, and, with your knowledge of the contents of Dr. Vachell's letter, still refusing, at my invitation, to meet the members of the Society to discuss this question—not in public, but in the proper place—a duly convened meeting; by asserting that we have influenced the Corporation to deprive you of this work, and by publishing such a base, unworthy and groundless charge in the press; by confusing the issue between yourself and the Society; by introducing in your last letter a complaint against the acts of private individuals without naming them, and further, by insinuating that by sending a printed list of members of the Society with the memorial that we wished it to appear that those gentlemen who were not present at the memorial meeting had signed the memorial.

It is well known to the members of our Society that you designed the present museum buildings in Working Street, and in preparing plans for the extension of the free library, now nearing completion, an extension of accommodation for the museum was contemplated but abandoned, and it is also well known that in addition to your services professionally you have given honorarily, as a member of the museum committee, valuable assistance and advice on the work of that committee. And these facts alone, without other information, would constitute a sufficient ground for myself, as an architect, to abstain from any interference with you in your claim to act as architect to the new museum and art gallery in Park Place; and moreover if you can prove to myself and the Society that you have either a legal or moral claim to this position I can assure you, as its President, that we will support you by every means in our power and in any manner you may suggest.

In conclusion, as a friend of yours, and in the interest of the profession in the town, I again repeat the suggestion contained in my short note of the 22nd ult., that I will call a meeting to discuss the question if you will promise to be present, and, in offering the suggestion again, I may state that we do not wish to discuss your "business affairs," but to know the ground of your claim to hold the position of architect to the

proposed museum in Park Place, which Dr. Vachell so distinctly denies. If a good one, I am certain that the Society will support you in it, for there is no desire to deprive you of what you consider "an honourably acquired engagement."—Believe me, very faithfully yours,

(Signed) F. M. BRUCE-VAUGHAN.

Edwin Seward, Esq., Cardiff.

FUTURE OF PLUMBERWORK.

ON this subject Mr. Peter Fyfe, sanitary inspector for Glasgow, delivered a lecture in the Waterloo Rooms. Ex-Bailie Crawford presided, and there were present Mr. John Gordon, I.A.; Councillors John King, Brechin and Dunn; Messrs. James Anderson (president), William Fyfe (vice-president), Robert Campbell (treasurer) and J. T. Renfrew (secretary), Master Plumbers' Association; Archibald Craig, secretary of the District Council, &c.

The Chairman having briefly introduced the lecturer, Mr. Fyfe began his address by a reference to the responsible nature of the duties the practical plumber had to perform. He found, he said, that in greater Glasgow there were 239 master plumbers, employing 1,151 journeymen and 239 apprentices. Of the masters 115 undertook steam and hot-water heating, 124 confined themselves to plumbing pure and simple, and 200 were prepared to assist in the distribution of water in the city at a pressure of 1,000 lbs. to the square inch. All recognised the fact that since the plumber came to add the extraction of sewage from the home to his first duty of supplying pure water, he jumped from being a tradesman yielding comfort and convenience into the position of a health protector or a health destroyer. He knew from experience in his official position that lives were yearly undermined and cut off through inefficient workmanship in pipes and drains. They would therefore all agree with him that no individual should be entrusted with the conception and construction of work who could not give evidence of a full knowledge of its principles and practice. Therefore the necessity for a State-protected register of the men who were accounted fit to fulfil the law. Not till then would the modern plumber be regarded as the trusted friend of every household instead of its deadly and most troublesome foe. Mr. Fyfe afterwards spoke of the possibility of the introduction of more rational methods of obtaining heat and power in large cities, predicting that in 1945 Glasgow would warm herself, cook her

food, and drive her motors by very different methods than those employed just now, and in these, he was convinced, the future plumber should have a predominant share. In New York in 1882 works were established to supply steam at a pressure of 80 lbs. per square inch to the citizens from central stations. Two main stations had been erected by the New York Steam Company capable of supplying high-pressure steam up to 19,000 horse-power per hour. The main wrought-iron pipes from these stations extended through nearly eight miles of streets, yielding power to between 500 and 600 steam-engines, but principally heat to public and private buildings. For a continuous supply of one indicated horse-power per hour a charge of about 3d. per hour was made, which for a working period of 3,000 hours during the year amounted to 9l. 7s. 6d. Small users paid more, viz. 12l. 10s. and large users paid less, or 7l. 10s. In Glasgow these charges would be greatly reduced, as both our fuel and our labour are much cheaper. Coming to the cost of heating, he found the charge was about 9s. 6d. for each 1,000 cubic feet of space heated during 182 days of the cold season at 24 hours per day. He estimated that at two-thirds of this cost the same thing could be made to pay handsomely in Glasgow. In connection with our refuse despatch works, the cleansing committee consumed in the furnaces of the destructors 94 tons of what was technically known as "soft core." He had found by experiment that the committee were in this way parting with a commodity they might be able to sell in the form of steam for 14l. 12s. 6d. nightly, or per annum of 3,000 working hours for 4,387l. 10s. Out of this sum which might be obtained for the steam, what might be termed the pure loss was its equivalents in coal at 7s. a ton, which amounted to 1,213l. 12s. 6d. per annum, and the fireman's wages, which of course were at present lost. The power of these furnaces, if utilised with suitable machinery, was capable of supplying 562 arc lamps of 2,000-candle-power, which would light on the low-tension system 19 miles of streets. He considered further that the Corporation were in quite an exceptionally good position for trying the power and usefulness of steam for heating and cooking in a few selected buildings near to any of their works, either in tenements belonging to themselves or by special arrangement in the property of private proprietors. Mr. Fyfe then proceeded to describe a system in operation in Paris for the transmission of compressed air from central stations, and showed its sanitary advantages as a motive power in factories, workshops and shops.

COUSLAND & MACKAY,

Ventilating Engineers,
150 HOPE STREET, GLASGOW.

The thanks of the meeting were given to Mr. Fyfe for his lecture.

In the course of the evening the Chairman, on behalf of the Worshipful Company of Plumbers, presented to each of Messrs. Francis M'Culloch, Robert Hunter, William Cunningham, and A. F. Whyte the bronze medal of the company for distinction gained in the department of plumbing exhibits at the National Workman's Exhibition held in London in 1893. The medal has been recently struck from the design of Mr. W. D. Caroe, and has been engraved by the celebrated medallist Mr. Allan Wyon. It is intended to mark in a special manner the company's sense of the supreme importance of maintaining a high standard of handicraft, skill and excellence of workmanship.

EDINBURGH SANITARY PROTECTION ASSOCIATION.

THE annual public meeting in connection with this Association was held in Edinburgh, Professor Sir Douglas Maclagan presiding. The secretary, Colonel Noble, read the eighteenth annual report, which stated that the Council had much satisfaction in being again able to point to such useful work during the past year. It was with regret that they had to record the recent death of Sir James Stewart Richardson, Bart., of Pitfour, one of their vice-presidents. The fact that forty-six persons had since January 1, 1894, become annual subscribers in Edinburgh and Leith, whilst only twenty-one signified their wish to withdraw, sufficiently indicated the growing confidence entertained by the public in the usefulness of the Association. Notwithstanding certain statements that had recently been made in the press and elsewhere, tending to show that the arrangement of the usual domestic sanitary appliances advocated by this and similar Associations was incompatible with their efficient protection from the action of frost in severe weather, the Council were distinctly of opinion that where the internal fittings and work generally were in good order, no greater difficulty should be experienced in keeping such appliances in efficient operation during periods of frost, when arranged in accordance with sanitary requirements, than when that arrangement was otherwise. It was the intention of the Council shortly to reprint and reissue a pamphlet explanatory of the precautions that should be taken in order to maintain domestic sanitary systems in efficient working order during frost.

THE LATE JOHN POWELL.

INDUSTRIAL art has sustained a heavy loss by the death which took place on Saturday at Blackheath, near London, of Mr. John Hardman Powell, the artistic head of the eminent Mediaeval firm of Hardman & Co., of Newhall Hill, Birmingham. Mr. Powell, who had been in failing health for some time past, was attacked by influenza about a week ago, and pneumonia supervening, he succumbed to the disease on Saturday last, the eve of his sixty-eighth birthday. According to the *Birmingham Post*, Mr. Powell was born in Birmingham on March 4, 1827. His father was William Powell, a well-known local brassfounder, who married Lucy, the daughter of John Hardman, the founder of the firm of Hardman & Co. John Powell early showed signs of artistic talent, and was placed with Mr. George Elkington, founder of the firm which bears his name, in order to learn modelling. His apprenticeship to modern art, however, was destined to be brief. About that time his uncle, John Hardman, was commencing the revival of Mediaeval art, both in metal-work and stained-glass, in conjunction with Augustus Welby Pugin, and he shortly afterwards removed his nephew to Ramsgate, where Mr. Pugin had his studio. Young Powell soon caught up with enthusiasm the spirit and traditions of his master's art, and rapidly became his right hand in all that related to design and drawing. Probably the happiest years of Mr. Powell's life were those spent in the Ramsgate studio. In 1850 he married Mr. Pugin's eldest daughter, Anne, who survives him. When Pugin died, in 1852, John Powell returned to Birmingham, and was shortly afterwards taken into partnership, together with his brothers William and James (the former of whom still survives), by their uncle, Mr. Hardman, and the firm then became known as John Hardman & Co., the title which it still retains.

Mr. Powell threw himself with energy and enthusiasm into his work, surrounding himself with a staff of congenial artists and students, and labouring often till a late hour of the night on the designs and compositions for which the firm had become celebrated. There are few churches or cathedrals in the country in which some examples of his art are not enshrined, and among those with which he was especially identified may be mentioned the west windows of Worcester Cathedral, and St. Martin's, Birmingham; the beautiful window in St. Chad's Cathedral, to the memory of the late John Hardman; and more recently the windows of the noble

church lately erected by the Duke of Norfolk at Norwich. Mr. Powell was no less happy in metal-work than in glass, and many of the choicest productions of the firm in grilles, rood-screens and altar-plate were from the designs of the deceased artist partner. Of late years, however, Mr. Powell's work had been practically confined to window-designing, owing to the separation of the metal and glass departments, and the establishment of a distinct firm for the carrying on of the former branch. Whilst deeply penetrated with the spirit of his master, the great Gothic revivalist, Mr. Powell was not wanting in the creative faculty, and his conceptions generally, whilst conforming to the canons of Mediæval art, exhibited a fancy and character which were all his own. He had a lofty ideal of the dignity of art, put his best work into everything he touched, and persistently refused to lower his standard to anything that was mean or false or *ad captandum*. Mr. Powell was fortunate in drawing around him a group of congenial workers who were quick to imbibe and carry out his ideas, and among them may be mentioned Mr. W. J. Wainwright (who has since achieved so eminent a position in another field of art), Mr. G. B. Maycock, and Mr. Dunstan Powell (the eldest son of the deceased). The two last-named artists, we may observe, are responsible for most of the more recent designs of the firm, with which they remain. Mr. Powell's modesty, amiability and charm of manner were on a par with his artistic qualities. He was naturally of a retiring disposition, and took no part in public life beyond delivering a few lectures at different periods to the students of the Birmingham School of Art, an institution in which he always took the warmest interest. Mr. Powell was not a prolific writer, but some of his lectures which have been published, and the paper on "Mediæval Art" which he contributed to the volume on the "Industrial History of Birmingham and District," prepared by Mr. Sam Timmins in connection with the visit of the British Association in 1865, gave evidence of diligent study, shrewd critical observation and considerable literary skill. A few years ago Mr. Powell left Birmingham to take up his residence at Blackheath, in order to superintend the London branch of the firm, situated in King William Street, Strand, whilst his partners, Mr. William Powell and Mr. John Hardman, continued to reside in Birmingham. Mr. Powell leaves three sons and seven daughters, several of whom are married. His remains were buried on Wednesday last at Ramsgate, near to his beloved master and father-in-law, Augustus Welby Pugin.

CIVIL AND MECHANICAL ENGINEERS.

THE above Society visited the works of the New City of London Brewery in Upper Thames Street, E.C., and the works of the Waterloo and City Railway now in course of construction. The members were conducted over the brewery by the company's brewer, Mr. J. B. Kibble, and their engineer, Mr. W. T. Harris. The brewery is an old-established one, and contains a large amount of machinery of considerable interest to engineers. The better part of the old machinery has been kept, and this is combined with modern machinery and apparatus. The members first inspected the pumping-engine and well. The latter, owing to the continual lowering of the water level under London (which is at the rate of one foot a year in the neighbourhood of this brewery), has been deepened and altered considerably since it was first sunk, the particulars of which were clearly pointed out by Mr. Harris by the aid of drawings showing various sections of the well and the strata through which it passed. Those present were then shown by Mr. Kibble the whole of the brewing process, from the taking in of the grain to its final sampling. They were shown the separator for the extraction of nails, dust, &c., from the grain; the malt-crushing rolls, the modern converter, a new and very interesting machine which is capable of dealing with 70 quarters of malt at one operation, and requiring 25 horse-power to work it. From the converter the members were taken to the mash tun-room, to the coppers, to the hop store constructed about 1825, the floor of which is supported by means of wrought-iron slings from the roof. The party then passed to the cooling-room, the fermenting-room, the yeast-room, the yeast coolers and presses, and finally to the racking-room, where the members were shown, among other things, an excellent barrel-lift of Mr. Harris's design. A hearty vote of thanks was accorded Mr. Kibble, who had been most courteous in his reception of the members, and to Mr. Harris, after which the party proceeded to the Waterloo and City Railway works, over which they were shown, in the absence of Mr. Hay, the resident engineer, by Mr. Knowles, the contractors' engineer, who explained in detail the work that was being done and the method of carrying it out. The length already completed of one of the tunnels, there being two, is a quarter of a mile, and their diameter is 13 feet each. Mr. W. R. Galbraith and Mr. J. H. Greathead are the engineers to the scheme, and Messrs. J. Mowlem & Co. are the contractors. The machinery used is of

modern date, the works are lighted by electricity both above and below ground, and an electrically driven locomotive conveys the spoil from the face of the heading to the central shaft, where it is raised and deposited into barges alongside. The shaft, which is in the river, enables the work to be carried on without disturbing in any way the thoroughfares under which the railway burrows, and further, there is a considerable saving in the cost of construction by this method of working. Mr. Knowles having been thanked the members dispersed.

A BUILDER'S ACCOUNT.

AT the Skipton County Court Mr. Edmund Ridley, Q.C., sat as official referee to hear an action in which the plaintiff was Mr. Oswald Lister, contractor, of Ilkley, and the defendant was Mr. James Lambert, of Ilkley, and of Glen Cottage, Skyrethornes, in Upper Wharfedale. The original writ was for the sum of 836*l.*, and was in respect to contracts in the building of Glen Cottage, Skyrethornes, of which property the defendant was owner. The sum of 278*l.* had been paid into court, leaving a balance of 558*l.*, which was now sued for. The defence set up was that the work at Glen Cottage, Skyrethornes, had not been properly completed, that the work done had been carelessly and negligently done, that excessive charges had been made, and that the work had extended over an unreasonable time, namely, from 1892 to 1894. The plaintiff stated that before the work was fairly completed he and Mr. Lambert had some words, and he (plaintiff) was dismissed from the job. The quarrel was with respect to the getting and dressing of stone, &c. Plaintiff estimated the uncompleted work to amount to about 34*l.* There had been a large number of contracts, estimates having been given at different periods from 1892 to 1894. In the autumn of last year plaintiff had made application to defendant to have a settling up, and refused to give Mr. Lambert an estimate for other work because a settlement had not been effected. In cross-examination it was endeavoured to prove discrepancies in the several contracts and in the time-sheets of the plaintiff's men. The Official Referee remarked:—Because plaintiff did his business well you wish to quarrel with him. He has done his business very well. Counsel further complained of Mr. Lister's extravagant charges with respect to drainage, &c., whereupon the Official Referee remarked that the defendant had agreed to such and such charges in the con-

tracts, and he must now stand by them. The Official Referee was afterwards informed that a consultation had been held, and that counsel had agreed as to an order, which was to [the effect that the defendant should pay the sum of 450*l.*, in addition to the 278*l.* paid into court, and costs. The Official Referee agreed to this course.

PATENTS.

[This List of Patents is compiled specially for this Journal by Mr. G. H. Rayner, of the firm of Rayner & Co., Consulting Patent Agents, 37 Chancery Lane, London, W.C., from whom all particulars and information relating to Patents may be had gratuitously.]

APPLICATIONS FOR PATENTS.

3474. Alfred Jones, for "Improvements in waste plugs for lavatories, sinks, baths and other purposes."
 3483. Frederick Lettice, for "Improvements in and relating to disinfecting apparatus for use in connection with drains, gullies, sinks and the like."
 3555. Lascelles Wood, for "Improved sanitary joint for tubes or piping."
 3561. Johannes Franz Kleine, for "Improvements in fire and damp-proof ceilings and walls."
 3611. Charles Talmage Bastand, for "Improvements connected with window-sashes."
 3669. Percy Richard Julius Willis, for "Improvements relating to windows."
 3677. Johannes Ehrcke, for "Improved means for rendering doors and windows draught-tight."
 3784. Andrew Cashin, for "Improvements in lift-up rim locks and latches for doors."
 3801. Mervyn Hardy Wrigley, for "An improved window-fastener."
 3896. Andrew Murray and Thomas Cochrane Highet, for "Improvements in and relating to sash-windows."

Architect and Contract Reporter.

NEW READING CASE.

To Librarians of the Public Libraries and Reading-rooms.—A new handsome Reading Case can be supplied at a nominal charge of 2s., by post 2s. 6d., on early application to the Publisher, 175 Strand, W.C.

SPECIAL NOTICE TO THE TRADE AND OTHERS.

[Extract from a lecture on Architects' Libraries by Professor T. Roger Smith, F.R.I.B.A., at University College, October 10, 1893.]

"Lastly, let me recommend the back volumes of the professional journals. In the course of years all sorts of architectural topics come up in the public press and before the professional societies, and if you hunt through the indexes of these publications when you are seeking for information which eludes you in books, you will often be rewarded."

There has been a considerable demand for the back numbers of *The Architect* during the last three or four months, which we have no doubt has arisen from the remarks made by Professor Roger Smith, as contained in the above quotation; but the consequence has been that our stock of back numbers is getting very low, and consequently, in future, the charge for back numbers of previous date to January 12, 1894, will be 6d. each.

A few of the back volumes may still be had, price 12s. each.

EDITORIAL NOTICES.

The authors of signed articles and papers read in public must necessarily be held responsible for their contents.

No communication can be inserted unless authenticated by the name and address of the writer—not in every case for publication, but as a guarantee of good faith.

Correspondents are requested as much as possible to make their communications brief. The space we can devote to Correspondence will not usually permit our inserting lengthy communications.

TENDERS, ETC.

** As great disappointment is frequently expressed at the non-appearance of Contracts Open, Tenders, &c., it is particularly requested that information of this description be forwarded to the office, 175 Strand, London, W.C., not later than 5 P.M. on Thursdays.

WINSOR & NEWTON'S

"Waterproof"

INDIAN INK.

This new preparation—made from genuine Indian Ink—has been introduced to meet the requirements of those Artists, Architects and Designers who wish to lay washes of colour over drawings in ink.

Unlike many so-called Indelible Inks, "Waterproof Indian Ink," when dry, will be found absolutely unaffected by subsequent wetting.

BUILDING TRADES' EXHIBITION.

A MEETING of the Consultative Council was held at the offices of the above Exhibition, 222 Strand, W.C., on the 12th inst., the following members being present:—Professor Banister Fletcher, J.P., F.R.I.B.A. (chairman); F. R. Farrow, F.R.I.B.A.; T. Locke Worthington, A.R.I.B.A.; J. E. Sears, F.R.I.B.A.; Thomas Minton, J.P.; E. Benedict, C.E.; E. J. Kibblewhite, A.S.A.; H. Greville Montgomery, G. M. Callender, and T. Freeman. It was reported that the R.I.B.A. had agreed to give assistance in judging the competitive handicraft, and that they would also lend models and drawings for exhibition. The City Companies had nominated the following gentlemen as judges to represent them:—Mr. W. Grellier, F.R.I.B.A.; Tylers and Bricklayers' Company; Mr. S. S. Hellyer, plumbers; Mr. James Greenwood, masons. Mr. B. E. Nightingale was nominated by the Clerk of Works Association. The following lectures were arranged for:—Professor Henry Robinson, M.I.C.E., on "Electricity;" Professor Banister Fletcher, on "Comparative Architecture," with oxy-hydrogen illustrations; Mr. Arnold Statham, barrister-at-law, on "Building Law."

TRADE NOTES.

A LARGE new clock and chimes, of Lord Grimthorpe's design, have been erected in the parish church of Halesowen, near Birmingham, and formally started by a former rector of Halesowen (Canon the Hon. F. G. Pelham). It is fitted up with all the latest improvements, and will doubtless be a boon to the inhabitants. The whole of the work has been carried out by John Smith & Son, Midland Clock Works, Derby.

THE Cottage Hospital, Fleetwood, is being warmed and ventilated by means of Shorland's patent Manchester stoves, the same being supplied by Messrs. E. H. Shorland & Brother, of Manchester.

AT the meeting of the Spalding Urban District Council a scheme was adopted for considerably extending and improving the public lighting of the town. It was also decided to erect another gasholder and carry out other improvements at the Spalding Gasworks, at an estimated cost of 3,000*l*.

VARIETIES.

IN connection with the Manchester, Sheffield and Lincolnshire Railway Extension to London, Mr. Edmond Fuller (Fuller & Fuller), the surveyor appointed by her Majesty's Board of Trade, has now made his award in respect of the several hundreds of houses required on the Eyre Estate in Hampstead and Marylebone for the purposes of this new line, and in respect of which it is understood a claim was made approaching some half a million of money. The amount of the award will now be deposited in the Bank of England, thus enabling the Company to take immediate possession of the several pro-

perties after settling with the occupying tenants and others many of whom have already quitted possession.

WE are informed that Mr. C. H. E. West, lately assistant surveyor to the Hackney Board of Works, has been admitted partner in the firm of Macer & Fitzwilliam, now carrying on business as auctioneers, surveyors, land agents and valuers, at 39 Cheapside, E.C.; 75 Crouch End Hill, N.; and (as surveyors to the London Financial Association) at the Alexandra Palace, Wood Green.

THE Finance Committee of the Liverpool Corporation have received sanction from the Local Government Board to borrow 60,000*l*. for reconstruction of the baths at the pier-head.

THE result has been published of the competition invited for the sewerage and sea outfall works at Oban. There were twenty-five designs sent in for selection. The Town Council appointed a professional assessor in Mr. T. Niven, C.E., Glasgow, and under his report the plans judged best in order of merit were—first, "Kerrera;" second, "Gravitation." The author of the first premiated design was found to be Mr. Woulfe Brennan, C.E., of Oban, and of the second Mr. Radford, C.E., of Nottingham.

THE head of Trapnell & Gane, a firm of art furnishers and cabinetmakers, well known in Bristol, has retired. Mr. Caleb Trapnell on the occasion entertained a large gathering of his friends and employes, who presented him with a handsome silver inkstand.

AN inquiry has been held in Halifax respecting the application of the Town Council to borrow 33,000*l*. to complete the markets, from the designs of Messrs. Leeming & Leeming.

AT the meeting of the Ossett Town Council it was proposed to begin the building of a municipal hall, estimated to cost over 8,000*l*. The consideration was deferred.

At the meeting of the Glasgow Association of Students of the Institution of Civil Engineers, Mr. D. Drummond, M.Inst.C.E., president, in the chair—a paper was read by Mr. James L. Proudfoot, Assoc.M.I.C.E., on "Two-Storey Goods Sheds at Cessnock Docks." The sheds have been erected by the Clyde Trustees on the north and south quays of the new Cessnock Docks, and differ from the older sheds in being double-storeyed.

CARVED OAK AND ANTIQUE DEPARTMENT, No. 204 TOTTENHAM COURT ROAD.

MR. A. MILLAR will read a paper on "Practical Carpet Designing" at the meeting of the Society of Arts on Tuesday.

AN inquiry has been held at Middleton into an application by the Town Council for sanction to borrow 38,710*l* for the execution of a scheme of sewerage and sewage disposal. The town clerk (Mr. F. Entwistle) explained that the original scheme was arranged by the engineers, Messrs. Hinnell & Proctor, of Bolton, or carrying out the international process of sewage purification by means of ferozone and lolarite, and comprised three rectangular precipitation tanks of a total capacity of 550,000 gallons, polarite filters of 1,200 square yards, sludge-pressing machinery, &c. The revised scheme now submitted has been arranged to include the improved form of continuous upward-flow circular tanks with the Candy sludge removal apparatus, whereby the sludge will be removed without interference with the continuous flow of the sewage; also clarifiers for the removal of all light flocculent matter, which otherwise would be deposited on the superficial layer of sand in the filters. By reason of this complete clarification of the tank effluent the engineer has been able to arrange the filters at the reduced area of 600 square yards, containing two layers of polarite, each 6 inches thick, working at double the speed of the original 6-inch layer filter. The filters will also be arranged with special aerating layers.

NOTES ON NOVELTIES.

Aspinall's "Wapicti" is a new washable distemper paint that can be manufactured in any tint, and which has been designed for application to plaster, stucco, brick, stone, cement, &c. It is capable of yielding good artistic effects by stencilling, and therefore adapted for livening up interiors by decoration, having a flat surface suited for the purpose. Among the advantages claimed for "Wapicti" are that on exterior work it dries with a surface impermeable to the most drenching rain, and can be used with advantage for farm dwellings, wooden or other houses, and general work on estates, that the effect obtained with it is far superior to that of flatted paint, and costs one-third less. It is very largely used for painting the walls of asylums, churches, hospitals, railway stations, schools, private houses, &c. We have recently tried Wapicti, and can quite endorse all that Messrs Aspinall have claimed for this paint.

A New Fire-escape.—We hear that Mr. H. Wybrow, of Birmingham, has invented a fire-escape of a novel description.

It can be fitted when not in use against the front of a house in the form of a balcony. It is ornamental in appearance, and is intended to be fixed beneath the windows of the sleeping apartment. In case of fire all that is necessary is to liberate a lever and one end of the balcony falls to the ground, and by an automatic arrangement the strips of metal forming the floor are converted into steps down which the inmates may descend in safety. The escape has been submitted to some of the leading surveyors and engineers of Birmingham, who have reported favourably upon its utility. It is especially adapted to large buildings, and may be made of any size and, we are informed, at a reasonable cost.

THE NEW FEVER HOSPITAL FOR GLASGOW.

THE fortnightly meeting of the Glasgow Police Board was held on the 11th inst., Lord Provost Bell presiding. An animated discussion, which lasted over an hour, took place in regard to the fixing of the contract for the mason, digger and brickwork of the new fever hospital at Ruchhill. When the tenders were opened the lowest offerers were found to be Messrs. William Steven & Sons. Subsequently the committee decided that the whole contract should be completed within two years, and they made that period of time a condition of the acceptance of the contract. Messrs. Steven & Sons wrote that they could not undertake the work within the period named. The next three lowest offerers were then written to, and Messrs. Morrison & Mason, Limited, having undertaken to finish the building in the stipulated time the committee recommended that the contract should be given to them, although their price was about a thousand pounds higher than that asked by Messrs. Steven. Councillor Martin moved that the matter be taken back for reconsideration, as he saw no pressing necessity for having the building completed in such a hurry. This was seconded, and in the discussion which followed it was remarked that it almost seemed as if the time limit had been an afterthought with a view to favour certain contractors. This statement was warmly repudiated by Councillor Crawford, the chairman of the committee, and the contract was by a large majority eventually awarded to Messrs. Morrison & Mason, Limited, whose contract price is 102,805*l*. A clause was ordered to be inserted in the contract making the contractors liable to a penalty of 10*l*. for every day they might exceed the time limit in completing the work.

199 Upper Thames St., London, E C.

DISCOVERY OF AN ANCIENT SEWER.

AN interesting discovery has been made in Chiswell Street, where the men in the employ of Mr. W. F. Coney, of 66 Fenchurch Street, who is erecting a large block of buildings on the vacant site at the corner of Milton Street and Chiswell Street, came across an enormous piece of brickwork 100 feet in length and about 10 feet or 11 feet in diameter, which has lain like a huge leviathan at the back of the Chiswell Street houses so long that it had passed out of the recollection of the oldest inhabitant. We are not able to fix the date of its construction or use, but as the houses which were built over it were some 150 to 200 years old, it may take us back to the days when John Milton was a resident in the neighbourhood, or even much earlier. What now remains of the work seems very solid and well constructed. The drain, we are informed by Mr. Coney, was full of refuse, which had so saturated the soil beneath it that his men had to go down 8 feet below to the "maiden soil" before they could find a satisfactory foundation for the iron columns which are to support the new building. It is somewhat startling to learn that for many years a coffee-shop kitchen, where the coffee for several generations of Londoners has been innocently brewed, stood directly over one portion of this not too savoury relic of our ancestors. Among the articles which the workmen found in the excavation of other portions of the site were some coins of the Georges, some small vessels of the early days of the manufacture of English pottery, a chimney ornament, a curious stone flagon (which might possibly be identified, as it bears a maker's mark), some fragments of stoneware, and a small quantity of tobacco-pipes of the days of Charles I. Some of these last, which we did not see, we are informed measured some 10 inches in length, and have small bowls and stems a quarter of an inch in thickness.

THE executive committee of the Association for the Promotion of Art and Music in the City of Glasgow have received from the architects a report on the progress of the art galleries in Kelvingrove Park during the month of February, from which it appears that building operations, till now at a standstill owing to the weather, are being resumed. The working of stone under cover is still in progress, and the construction of the main drain has, in spite of the severity of the weather, been completed.

WORKHOUSE ACCOMMODATION IN LIVERPOOL.

AT the meeting of the Liverpool Workhouse committee on the 7th, the following communication from the Secretary of the Local Government Board was read:—

"I am directed by the Local Government Board to state that they are informed through their inspector (Mr. Jenner Fust), that the select vestry of the parish of Liverpool have postponed the consideration of the report upon the accommodation at the Brownlow Hill Workhouse which was sent them in August last until the removal of certain of the inmates, for whom accommodation is being prepared at Kirkdale, has been effected. The Board consider the question of making further provision for the indoor poor of the parish of Liverpool to be of such pressing importance that they are unable to acquiesce in any avoidable postponement of its consideration. They would remind the select vestry that the class of inmates it is intended to remove to Kirkdale is that of the healthy adults, and that their removal will in no appreciable degree affect the accommodation for the sick nor enable the attic wards of the male and female hospitals to be vacated. The Board desire to point out that the vestry in their letter of October 23, 1894, admitted that the time had arrived when the necessity of providing further accommodation for the indoor poor must be recognised, and that they also concurred with the view taken in the above-mentioned report, that nothing can ever render the attic wards of the male and female hospitals suitable for permanent occupation by any class of hospital patients. The Board must request that the whole subject may receive the earliest and most serious consideration of the vestry, and that they will, with the least possible delay, submit for the Board's consideration a comprehensive and adequate scheme for providing satisfactory accommodation for the indoor poor of the parish of Liverpool."

The Chairman said that he had been rather in favour of

OUR HEALTH IN WINTER.—Dr. Andrew Wilson, writing in *Lloyd's Newspaper* on diet, says: "The teaching of nature should never be neglected, and in the matter of winter food let us see we are not wrong, and take sufficient fat, for the changes that result in the wear and tear of our bodies are lessened in intensity by the fat of food, and the need for flesh is always less when fat forms a due proportion of our diet." The Doctor proceeds to enumerate natural products that are admirable, among them "Cocoa" with its contained Cocoa Butter. Relatively to this it may be said that EPPS'S PREPARED COCOA retains all the constituents of the natural Cocoa, including the oil or butter, intact.—ADV.

postponement of the subject, but in view of this letter he was now of opinion that the time had come to take the matter up. Every section was overcrowded; and if they were to build a new workhouse, which was very likely to be the case, the idea was to build it elsewhere. They had now no room for classification, and that was the thing they would have to consider in building a new workhouse.

It was decided to leave the question to the decision of the vestry.

HULL MASTER BUILDERS' ASSOCIATION.

THE annual dinner of the Hull Master Builders' Association was held at the Grosvenor Hotel.

The president (Mr. T. Goates) occupied the chair, and was supported by the Mayor, Mr. Knowles (vice-president), Councillors Skinner, Wharram, Newham and Scott; Messrs. W. A. Gelder, John Hancock, J. Pantom, G. Houlton, Good, Townsley, J. Temperton, Peers, F. Sweeting, Sangwin, B. Robinson, Moody, Leake Bros., Bray, Goates, jun., W. Drury, B. Nicholson, Beevers, W. Beal, Rowland, W. Bailey, Carr, Caley, Quibell and Son, W. Hodgson, Southern, Wright, W. Harrison, J. Beal, Watson, Thorpe, Gaskill, Marsden (treasurer), Stanley (secretary), &c. After the tables had been cleared, and the usual loyal toasts submitted and heartily drunk, Mr. Vincent Knowles, in submitting the "Army, Navy and Volunteer Forces," said there were several battleships yet to be constructed, and he hoped that the Hull firm would be fortunate in securing a contract, thus being a boon for the good old town of Hull.

Mr. F. H. Pearson thought there would be no difficulty in getting ships up to the contract speed, and even perhaps a knot or two faster. He hoped that Hull would obtain still further contracts, for now was the time to build ships, with the price of iron, material and labour. There was plenty of idle labour and they in Hull could well do with the employment of a thousand additional men. Now was the time to do it, and with the employment of further men he was sure the people would not grumble at paying the money.

The President said before they went further with the speeches he would, on behalf of the Association, thank the Mayor for his presence amongst them that evening. That was the second time he had been the Mayor of Hull, and he trusted that he would be so for the third year in succession. It was with great inconvenience that the Mayor attended their annual dinner for the second time, and it showed his appreciation of them as a body.

Mr. James Townsley, in submitting the toast of "The Mayor and Corporation," said he was sure he could extend the same hearty and cordial welcome to the Mayor as the President had done. They were pleased to see him amongst them. He was sure that everyone present would unite with him in congratulating his Worship the Mayor not only upon his promotion to the aldermanic bench, but also on his re-election for a second year to the high and noble position of being the chief magistrate of Hull. They had had many good mayors, but he was sure that they rarely had had one who had so ably conducted the affairs and business of their town as Alderman Richardson, and he did not think any other mayor had had such an united confidence, both of his colleagues and ratepayers generally, as their present Mayor. He thought there was sadly too many grumblers in Hull at the present time. He was referring more particularly to some of the ratepayers who resorted to public letter writing. It would be better if these people rather devoted themselves to the support of the Mayor and Corporation—better for them and the town generally. He did not agree with some people that Hull was half a century behind the times, for as good work was being done in Hull at the present time as ever was. Their present Mayor was always charitably disposed towards alleviating the great distress in the town, and ever ready to appeal on their behalf. He had great pleasure in submitting the toast.

The Mayor, in responding, expressed his sincere thanks for the cordial manner in which they had welcomed him. He was pleased to hear that the efforts he had endeavoured to make had, in their opinion, been successful. He could only say that one reason why his term of office had been so far—in the opinion of many gentlemen who had been kind enough to say so—successful was that he had been surrounded by a loyal band of colleagues who had given him their hearty and sympathetic support. That Association was well represented in the Hull Town Council. Some of its most prominent members were connected with their trade. Mr. Skinner, Mr. Wharram and Mr. Scott were men most earnest he was sure in their desire to promote the public welfare. In his opinion it was one of the most singular and most pleasing things that they had to remember in connection with this nineteenth century, the vast amount of voluntary work that was given by gentlemen who were engaged in busy commercial lives—in philanthropic work, in social undertakings, in educational work, and in many spheres—gentlemen who were willing to give their services without any hope of fee or reward, for the benefit of

their fellow men. He could say, from a long experience in the Corporation, that so far as his experience went the gentlemen who sat upon those benches did not go there to represent their own interest, but to endeavour, so far as they could, to advance the interests of the town and promote its welfare. He asked them not to think that they were indifferent to the expenditure which was absolutely necessary to be incurred in the good government of a town like Hull. The estimates which were brought forward from time to time were carefully considered by the various committees who had charge of the expenditure in their various departments. He was sure that nothing gave them greater concern than the advances which had necessarily to be made from time to time. The greatest interest was taken in their estimates, and if they had to be increased it was only by a strong sense that public interest demanded it. He need not tell them that, whilst they had many public duties to perform, the state of the town generally excited their grave attention—he meant the present unfortunate distress that existed in their midst. He believed that for some time building operations had been practically suspended, necessarily causing a vast amount of distress. It must be pleasing to those present that the members of their police force, in response to an appeal he himself made to them, had come forward so generously and worked so assiduously for the relief of the distress of the children. At all the branch police stations he believed that free meals were given to those in absolute need. He did not know any better method of distributing relief than by the hands of the police, for they were acquainted with nearly all the deserving cases in the town. That Association represented an important interest in the country at large and the allied trades connected with it. It was sometimes said that the work done to-day was not so good as that done years ago. But he took an exception to that remark. He thought the builders and architects of to-day were quite equal to any that had gone before. If any blame was to be given he thought it must be given to the public, who wanted houses that were really worth 50% or 60% a year for 40%. The people who criticised the work of the builders should remember that if they were willing to pay the price they would get as good an article now as ever could be produced by the art of the builder.

Mr. W. A. Gelder, in proposing the "Hull Master Builders' Association," said that it was wise for an architect, as he was, to desire the success of the master builders. They were so closely allied that success to one meant, he thought, success

for the other. Their Association represented a considerable number of the community of Hull. The employers of labour present, either directly or indirectly, were a great multitude, and therefore, in proposing success to the Hull Master Builders' Association, in one respect he was wishing success to the town of Hull generally. They were living in a time when work was in a state of languor. They were not living in prosperous times, but he trusted that would soon be rectified. That Association was formed not so much as an organisation to raise prices or form a ring to keep up the cost of buildings, but to insure good work being accomplished. Some people imagined that that organisation existed simply to regulate prices, but that was not the chief factor. Their object in combining was to insure a better class of work being accomplished in their midst, and to meet the combinations which were formed in other directions. He had not one word to say against combinations of labour, because in this present age they appeared to be a necessity, but so long as they were a necessity for one party they were for another. He was of opinion that the time would come when all strikes and lock-outs and friction between employer and employed would be avoided for consideration of each other.

The President, in responding, said their Association was not formed as a defiance but a defence. He had been in the trade for forty years, and his experience was that more consideration should be shown to the working men. If they treated the men well his experience was, though there were black sheep in every flock, that they treated the masters well. The men were not so black as they were painted. If they would give them more consideration than they did, he was sure it would be a paying investment. He hoped that strikes were a thing of the past, and that disputes would before long be settled by conciliation or by arbitration, for strikes never did any good to anyone, but caused many to suffer and drove trade out of the country. If all the members of the Association would stick to it and its principles he was sure that the sun of peace and prosperity would never cease to shine on that Association.

Councillor Skinner ably submitted "The Architects."

Mr. P. Gaskell, in responding, thought that if the new Municipal Buildings were ever to be erected, only Hull architects and builders should be employed, for he was sure they could show as good a return as any from other towns.

Councillor Wharram, in submitting "The Town and Trade of Hull," drew attention to the great amount of distress in the

town, and thought that that Association should do something to alleviate it. He suggested a subscription on the spot, and he would head it with a guinea, to be given to the Chief Constable to help to feed the poor destitute children of Hull.

Mr. T. Liggins suitably responded.

THE CARDIFF IMBROGLIO.

IN addition to the letters already printed the following have appeared in the Cardiff *Western Mail* :—

Sir,—May I ask Mr. E. M. B. Vaughan, through your columns, to do me the favour of taking this letter to you as an answer to one from him in this morning's *Western Mail*? I am writing to him to thus oblige me, and to so save time and trouble. Mr. Vaughan complains of publicity being given to this matter. I should have thought such a complaint at present a little out of date, and I am anxious to emphasise the fact that nothing is more needed herein than the unbiassed inquiry which publicity insures. Mr. Vaughan thinks this question of "little or no public interest." The careful attention which the press has given it has, however, declared otherwise. But if we are to discuss the question of publicity we must go back a little, and look for certain portentous paragraphs sent to the press before any meeting of architects on this matter, and which gravely set forth the resolution it was intended to carry. After that meeting we shall find further paragraphs duly announcing the weighty decision arrived at, viz. that public competition was to be petitioned for. One must suppose that "public interest" was then fully satisfied. At any rate, the publicity of January, 1895, was evidently a most acceptable and good thing; but the publicity of March, 1895, is bad—very bad. Yet the only discernible difference is that the first was supposed to have acted the play through and rung down the curtain, whilst the last varies from it only in disclosing the staying powers of that most uncompromising of all young persons, whose proper abiding place is usually at the bottom of a well. Those January shots (which included the architects' petition as a final broadside), though doubtless intended to kill at short distance, somehow missed fire. I still suspect the cause to be (in spite of Mr. Vaughan's letter this evening, that the gun was overloaded—too many names, in fact, rammed into it along with the recognised lawful charge. Later on, ten days ago, I wrote a letter of regret to Mr. Vaughan for non-attendance at the annual dinner of the architects, adding to it a review of the respective relations of

the Society and myself. It was, of course, too much to expect that missive to be discussed there, but I did expect the usual courtesy of some slight reference to the fact that the ex-president had written regretting non-attendance. Finding the letter was wholly suppressed, and recollecting that a previous letter of importance from me to the secretary had met with a similar fate, I felt that those inquiries which representatives of the Press were then making from me deserved very thoughtful recognition, and, on request in each instance, I most willingly handed over proper copies for their use on it being pointed out that Mr. Vaughan would probably persist in remaining reticent, and withholding my letters from those gentlemen's inquiries. I can appreciate Mr. Vaughan's surprise on his seeing my letter in print before he could reply to it, for I had a similar experience last week with his, which I saw in print some time before receiving it. But, seriously speaking, I feel it must be recognised that many features of this matter are most properly discussible in the Press, to which obligation is due as affording some means for what is just and right in it being made plain. I shall clear up one of Mr. Vaughan's chief points at once by directing him to his letter this morning, to observe a small but important change of phraseology which he makes in quoting my letter. He quotes :—"You say that we have influenced the authorities to such an extent as to cause you to be deprived of the position," &c. He will see my actual words to be :—"The course which has been followed in endeavouring to so influence the authorities as to cause me to be deprived," &c. Respecting the first quotation, Mr. Vaughan expresses his view that "such action would stamp the conduct of those present at the architects' memorial meeting as dishonourable and unprofessional." Of his two adjectives I will not adopt the first, but I thank him for his application of the second, and I willingly agree with him that any assertion that the architects "have influenced the Corporation to deprive" me of this work "is a base, unworthy and groundless charge." They certainly have not done so—as yet.

Now as to the true pith of this question. Mr. Vaughan has previously made it clear that the Architects' Society action—good or bad—was based on two facts; the one a letter from Dr. Vachell, the other a statement by Mr. Edwin Corbett, and my making further reference to these gentlemen is necessary if I am to meet Mr. Vaughan's charge that I am "confusing the issues." Therefore I will now try to clear them, especially as a little reticence on my part hereon may have given some colour of reasonableness to Mr. Vaughan's desire.

157 STRAND, W.C. (Four Doors from Somerset House), LONDON.

With Dr. Vachell, as a friend of years past, and a truly enthusiastic colleague in this and many allied matters, I will find no fault if he does what he has every right to be doing, viz. desiring to see someone rather than myself acting as architect for the museum. His letter does not appear to me to do more than express his own personal views, and his statement that the building committee had not been called together is absolutely correct. But how "several other members" of the museum committee became "firm in their opinion that I have no claim, legal or moral," or what reasons they may have for the said firmness of opinion, is, I confess, a bit puzzling, seeing they had "not even been called together," which non-calling I can corroborate, for no committee of the museum has ever discussed my claims, nor has ever been in the least degree commissioned to pronounce upon them. I am really curious to know these "other members," for I feel assured I have never yet met them. And if they do exist, their pronouncements respecting my position are in any case quite *ultra vires*. That fact must have been quite self-evident to the architects; but yet note that it was accepted as an ample basis for a number of professional gentlemen to resolve on attacking the well-recognised practice of one of their number. But there is the statement of Mr. E. Corbett, speaking not only as an architect desiring competition, but as an agent of the Bute estate, and who is stated to have told the meeting, in respect to the Park Place site, that "the land was let or sold to the Corporation with a condition that the design for the new building should be the result of open competition." There is here some extraordinary mistake. I know the agreement well—officially, indeed, for I have acted as surveyor on behalf of the Corporation in respect to it—and I say unhesitatingly that there is no such condition in it, nor indeed any reference whatever to the question of architect suggesting such an interpretation. Further, I feel convinced that the Corporation of Cardiff would not have accepted such a condition in their agreement.

Now, I would ask Mr. Vaughan seriously, Ought these bases, each containing plenty of opportunity for error or misunderstanding, to have been accepted by a meeting of gentlemen as sound and business-like causes of action at a moment when they were dealing with a matter so closely affecting the professional status of a colleague? And should these have been sufficient to prompt them to at once cast aside as unworthy of acceptance that colleague's written assurances?

I will only refer to Mr. Vaughan's strictures referring to my

complaint against acts of individual architects by reminding him that he has pressed me (and still presses me) to meet the Society of Architects to discuss this business with them; that it is, therefore, necessary for me to thus declare that certain of those whom he would claim to put in the position of discussing my matter with impartiality cannot by any possibility do so. I have consistently, from the first moment, found myself unable to recognise that the architects have any place whatever in this matter, until they may possibly be officially called in. Any other attitude on my part would be merely weakness, and I look to the authorities alone for some issue to the present conditions.

But let me reciprocate with every sincerity Mr. Vaughan's personal expression of friendliness. So far as he is concerned, I accept as sufficient and satisfactory his statement that certain facts alone (which he names) constitute a sufficient ground for his abstaining from interference with my claims. His attitude as a professional man has not in years past and would not cause me any anxiety in respect to points of fairness and professional etiquette. I congratulate him on the excellent show he has at length made for the other side, and I sincerely hope his year of office will yet yield some case more worthy of the chivalrous spirit in which he has set himself to obliterate the blemishes in this one.—I am, &c.,

Cardiff: March 4.

EDWIN SEWARD.

My dear Seward,—Your letter in to-day's *Mail* and yesterday's *Evening Express* is a reply to mine of the 2nd inst., and I am presumably expected to answer it. I may say at once that I quite agree with you in saying that "the publicity of January 25 was a good thing," and that "the publicity of March and February is bad, very bad." The publication of such a resolution as the Society passed on January 24 was a legitimate subject for publication, for it dealt with a public question, viz. the proposed museum and art gallery in Park Place. The error into which you have fallen from the first, and which you are so persistent in proclaiming, is the idea that we were by that resolution interfering with you personally in "your business affairs," "attacking the well-recognised practice of one of your number," "attempting to deprive you of an honourably acquired engagement," &c. No such ideas as these ever entered our minds, and that is amply borne out by the first part of the resolution, viz. "That unless they have already pledged themselves to any architect." This certainly covered your claim to act as the committee's architect, and if

you had no claim and as we were led to believe would be the case, a competition advertised then, at any rate, we did, by the latter part of the resolution, what I know and feel would be your desire and have your sanction. We asked the committee that the competition should be open and conducted on the lines laid down in the suggestions of the Royal Institute of British Architects. But the publicity given to your letter of February 21 and that of the 1st inst. is quite another thing, and to quote you again, "Bad, very bad," and for this publicity you are entirely responsible. You sent or caused the representatives of the Press to be sent here to interview me, and on my refusing at their suggestions to give them a copy of your letter of the 21st ult., they told me whether I gave them a copy or not it would appear in their respective papers next morning, and as no one but myself had seen that copy of your letter it was evident to me that you had given copies to each paper; and this action of yours forced me, very reluctantly, to give them an account of our meeting; and further, I had scarcely read your letter of the 1st inst. before I read it in the *Express*, and the first and only letter I have sent to the Press on this subject is that of the 2nd inst., in which I endeavoured to give a plain unvarnished tale of the whole course of our proceedings.

I have already given my reason in public for not reading your letter of the 21st ult. at the annual dinner. It would have been quite out of place and character with that gathering to have even introduced a mere suggestion of your reason for staying away, and I believe I was perfectly justified in suppressing, to use your word, that letter on such an occasion. But of the fate of your letter to Mr. Coates Carter, dated January 24, I am not quite so certain. I am almost positive I did read that letter to the meeting myself, and if it was not read it was entirely my fault. But I will allow Mr. Edwin Corbett to answer another question of yours, and at the same time to correct an error of mine:—

[COPY.]

Castle Street, Cardiff: February 23, 1895.

Dear Vaughan,—I am very sorry to see in this morning's print that Mr. Seward has thought it proper to send his letter to the papers. I am taking the liberty of writing to say I entirely agree with the line you have taken, and shall be pleased to attend a meeting of the Society with the object of trying to convince Mr. Seward that no one in the Society wishes to prejudice him in any way. I do not know if by

what I said I left a wrong impression on your mind, or whether you are wrongly reported; but no condition was made when the land was let that the design should be by competition. I asked the members of the committee who saw me as a personal favour that it should be so, and strongly urged it—of course, without the least idea that Mr. Seward considered he had any claim to the work. There is no necessity to correct this in the Press, as the less public correspondence there is on what is really only a personal matter the better.—Yours faithfully,

EDWIN CORBETT.

There is only one other point to refer to in this last letter of yours and I have done. You have spoken of my suggestion that you should meet the Society as an inconsistent one. To quote you once more, "Your inconsistent suggestion that I should discuss my business affairs with gentlemen who are concerned in an attempt to deprive me of an honourably acquired engagement." You have acquitted me personally of this serious charge and I thank you for it, but you still hold my colleagues guilty. The age of chivalry is not over, and as I have undertaken a very thankless and unprofitable task, I may say, in their defence, it is not so long ago that you came to us and told us that some of the members of the old free library committee intended to deal unfairly with you with regard to the extension of the present building. But what did we do then? We knew that you had a decided claim—a strong one from a professional point of view—to act as their architect, and we supported you in it and readily consented to sign a memorial in your favour. And I will ask you to believe that the same spirit of fairness and justice and right professional dealing which characterised our conduct then has guided us in this matter all through, and will characterise our conduct in the future, and it is in this spirit I ask you once more to meet us to discuss this question in the proper place and not in the public Press.—Believe me, very faithfully yours,

(Signed) E. M. BRUCE-VAUGHAN.

Edwin Seward, Esq., F.R.I.B.A.,
Cardiff: March 6.

Sir,—A desire to close this correspondence (at least until matters progress) must be my excuse for brevity respecting the letter from Mr. E. M. B. Vaughan in the *Evening Express* this evening. The Architects' Society first gave the public one part of a case. I have, therefore, aided in ventilating a further necessary part. Having already spoken of Mr. Vaughan's thankless tasks, and accepted his candid admissions,

why need I say more? His points are previously covered except one; on that one I gladly express appreciation of the fair professional attitude of Mr. Vaughan and some other local architects in reference to the free library building in 1890, and I believe he would admit that there has been occasion since when he did not find me forgetful of it. The sharp and unnecessary contrast between the architects' action in 1890 and 1895 is responsible for this correspondence.—I am, &c.,

EDWIN SEWARD.

THE NEW FACTORIES AND WORKSHOPS BILL.

THE following are among the provisions of the Bill which is now before the House of Commons:—

Sanitary Provisions and Safety.

A factory shall for the purpose of section 3 of the principal Act, and a workshop shall for the purpose of the law relating to public health, be deemed to be so overcrowded as to be dangerous or injurious to the health of the persons employed therein, if the number of cubic feet of space in any room therein bears to the number of persons employed at once in the room a proportion less than 250, or during any period of overtime 400 cubic feet of space to every person.

Provided that the Secretary of State may, by order made in accordance with section 65 of the principal Act, modify this proportion for any period during which artificial light is employed, and may by like order, as regards any particular manufacturing process or handicraft, substitute for the said figures of 250 and 400 respectively any higher figures, and thereupon this section shall have effect as modified by the order.

A court of summary jurisdiction may, on complaint by an inspector, and on being satisfied that any place used as a factory or workshop or as part of a factory or workshop is in such a condition that any manufacturing process or handicraft carried on therein cannot be so carried on without danger to health or to life or limb, by order prohibit the place from being used for the purpose of that process or handicraft, until such works have been executed as are in the opinion of the court necessary to remove the danger.

If an inspector gives notice in writing to the occupier of a factory or workshop that any place in which work is carried on for the purpose of or in connection with the business of the factory or workshop is injurious or dangerous to the health of

the persons employed therein, then if the occupier, after the expiration of one month from receipt of the notice, gives out work to be done in that place, and the place is found to be so injurious or dangerous, he shall be liable, on summary conviction, to a fine not exceeding twenty pounds.

The traversing-carriage of any self-acting machine erected after the commencement of this Act in a factory shall not be allowed to run out within a distance of 18 inches from any fixed structure not being part of the machine, if the space over which it so runs out is a space over which any person is liable to pass, whether in the course of his employment or otherwise.

Provided that if the machine is on the same site as and is substituted for a similar machine existing before the commencement of this Act, the existing distance, if less than 18 inches, shall for the purposes of this section be substituted for the said distance of 18 inches.

Where any matter in difference is referred to arbitration under section 8 of the Act of 1891, the arbitrators or umpire may, on the application of any of the workmen employed in the class of employment to which the arbitration relates, and on such security, if any, as may appear to the arbitrators or umpire sufficient to provide for the costs of and consequential on the application, appoint any person to represent the workmen, or any class of them, on the arbitration, and any person so appointed shall be entitled to attend and take part in the proceedings of the arbitration to such an extent and in such manner as the arbitrators or umpire may direct, and shall be subject to the same liability with respect to costs as if he were a party to the arbitration.

Section 82 of the principal Act, which provides penal compensation to persons injured by neglect to fence machinery, shall extend to any death or bodily injury or injury to health in consequence of the occupier of a factory or workshop having neglected to observe any provision of the Factory Acts or any special rule or requirement made in pursuance of the Act of 1891.

Special Rules and Requirements.—Laundries.

1. The Factory Acts shall apply to every laundry which is carried on by way of trade or for purposes of gain:—

(i.) If steam, water, or other mechanical power is used in aid of the laundry process, as if the laundry were a non-textile factory; and

(ii.) In any other case, as if the laundry were a workshop.

2. In the case of every laundry worked by steam, water or other mechanical power.

WOOD BROKERS,

108 BISHOPSGATE STREET WITHIN E.C.

(a) A fan or other means of a proper construction shall be provided, maintained and used for regulating the temperature in every ironing-room, and for carrying away the steam in every washhouse in the laundry; and

(b) All stoves for heating irons shall be sufficiently separated from any ironing-room, and gas irons emitting any noxious fumes shall not be used; and

(c) The flooring shall be kept in good condition, and drained in such a manner as will allow the water to flow off freely.

A laundry in which these provisions are contravened shall be deemed to be a factory not kept in conformity with the principal Act.

3. Nothing in this section shall apply to any laundry in which the only persons employed are members of the same family dwelling there.

4. The exception created by section 53 of the principal Act with respect to overtime shall apply to laundries.

Docks, Building Works, &c.

1. The following provisions of the principal Act, as amended by subsequent enactments, including this Act, namely:—

(i.) Sections 5 and 82, with respect to the fencing of machinery;

(ii.) Section 31, with respect to notice of accidents; and

(iii.) Section 68, with respect to the powers of inspectors; and the provisions of this Act with respect to the register of accidents and the formal investigation of accidents, shall have effect as if—

(a) Every dock, wharf, quay and warehouse, and

(b) Any premises on which machinery worked by steam, water or other mechanical power is temporarily used for the purpose of the construction of a building or any structural work in connection with a building, were included in the word factory, and the purpose for which the machinery is used were a manufacturing process, and as if the person who by himself, his agents or workmen temporarily uses any such machinery for the before-mentioned purpose were the occupier of the said premises; and for the purpose of the enforcement of those sections the occupier of a dock, wharf, quay or warehouse, and the person so using any such machinery, shall be deemed to be the occupier of a factory.

Tenement Factories.

Where mechanical power is supplied to different parts of the same building occupied by different persons for the purpose

of any manufacturing process or handicraft in such manner that those parts constitute in law separate factories, the owner (whether or not he is one of the persons so in occupation) of the building (which building is hereafter in this Act referred to as a tenement factory) shall, instead of the occupier, be liable for the observance, and punishable for non-observance, of the following provisions, namely:—

(a) Section 3 of the principal Act, with respect to the sanitary condition of a factory; and

(b) Sections 5 and 82 of the principal Act, with respect to the fencing of machinery in a factory, except so far as those sections relate to such parts of the machinery as are supplied by the occupier; and

(c) Section 19 of the principal Act, with respect to the notices to be affixed in a factory and the matters to be specified therein; and

(d) Section 33 of the principal Act, with respect to the limewashing and washing of the interior of a factory, so far as it relates to any engine-house, passage or staircase, or to any room which is let to more than one tenant; and

(e) Section 36 of the principal Act, with respect to the removal of dust, so far as that section requires the supply of pipes or other contrivances necessary for working the fan or other means for that purpose; and

(f) Section 78 of the principal Act, with respect to the affixing of an abstract and notices.

In a tenement factory the period and times specified in the notice affixed in accordance with Section 19 of the principal Act shall apply to all the factories in the building, except so far as they may be modified for any particular factory in the building by a special notice in the prescribed form affixed in that factory by the occupier thereof.

Sections 8 to 11 of the Act of 1891 shall, if and as far as in the case of a tenement factory the Secretary of State by order so directs, apply as if the owner of the factory were substituted for the occupier.

The provisions of this Act with respect to the power to make orders in the case of dangerous premises shall apply in the case of a tenement factory as if the owner were substituted for the occupier.

Where, by or under this section, the owner of a tenement factory is substituted for the occupier with respect to any provisions of the Factory Acts, any summons, notice or proceeding which for the purpose of any of those provisions is by the said Acts or any of them authorised or required to be served

COMBINED STAYS AND FASTENERS FOR CASEMENTS AND FANLIGHTS.

WE beg to call your special attention to our Patent Combined Stay and Fastener, which, from its great advantages and easy mode of use, can well claim a superiority over the common kinds. You will notice that this Fastener has no complex system of working, is easy to fix, and, whether the casement is open or shut, does not project into the room, but hangs down the centre of the sash free from curtain or blind. The advantage of this Patent Fastener is that, being fixed in the centre of the sash, it affords protection against sudden gusts of wind when open, and keeps the sash safely closed when shut, as it acts as a fastener for the casement as well as a stay. Each of the three kinds of Fasteners affords the same advantages in all respects, as, though varying in shape, size, and price, are only different ideas of the same method. These Casement Fasteners can be used both for wood or iron, for single or double casements. The special pattern is used for fanlights to open outwards, and all can be used both for right or left hand. We can supply these Fasteners in any number of links, according to the extent the casement is required to be opened. We may also note that the Fasteners are well made and finished, can be had both in brass and iron, and are, therefore, well suited for any kind of residence. Quotations and further information will be given on application. Also testimonials. Please state in ordering whether

A large number already in present use giving full satisfaction. Unrivalled. you require them for single or for double casements.

Stay and Fastener shown in Action.

Cases for Binding the Architect.—Price Two Shillings. Office: 175 Strand, London, W.C.

on or taken in relation to the occupier, is hereby authorised or required (as the case may be) to be served on or taken in relation to the owner.

For the purpose of the provisions of this Act with respect to tenement factories, all buildings situate within the same close or curtilage shall be treated as one building.

Where grinding is carried on in a tenement factory, the owner of the factory shall be responsible for the observance of the regulations set forth in the first schedule to this Act.

In every such tenement factory it shall be the duty of the owner and of the occupier of the factory respectively to see that such parts of the horsing chains and of the hooks to which the chains are attached as are supplied by them respectively are kept in efficient condition.

In every tenement factory where grinding or cutlery is carried on the owner of the factory shall provide that there shall at all times be instantaneous communication between each of the rooms in which the work is carried on and both the engine-room and the boiler-house.

A tenement factory in which there is any contravention of this section shall be deemed not to be kept in conformity with the principal Act, but for the purposes of any proceeding in respect of a provision for the observance of which the owner of the factory is responsible, that owner shall be substituted for the occupier of the factory.

Regulations as to Grinding in Tenement Factory.

1. Boards to fence the shafting and pulleys, locally known as drum boards, shall be provided and kept in proper repair.
2. Hand rails shall be fixed over the drums and kept in proper repair.
3. Belt guards, locally known as scotchmen, shall be provided and kept in proper repair.
4. Every floor which is constructed after the commencement of this Act shall be so constructed and maintained as to facilitate the removal of slush, and all necessary shoots, pits and other conveniences shall be provided for facilitating such removal.
5. All existing floors shall be kept clean of accumulations of mud and slush.
6. Every grinding-room or hull which is established after the commencement of this Act shall be so constructed that for the purpose of light grinding there shall be a clear space of 3 feet at least between each pair of troughs, and for the purpose

of heavy grinding there shall be a clear space of 4 feet at least between each pair of troughs, and 6 feet at least in front of each trough.

7. The sides of all drums in every grinding-room or hull shall be closely fenced.

8. No grindstone shall be run before any fireplace.

9. No grindstone erected after the commencement of this Act shall be run before any fireplace or before any door or other entrance.

PATENTS.

[This List of Patents is compiled specially for this Journal by Mr. G. H. Rayner, of the firm of Rayner & Co., Consulting Patent Agents, 37 Chancery Lane, London, W.C., from whom all particulars and information relating to Patents may be had gratuitously.]

NEW READING CASE.

To Librarians of the Public Libraries and Reading-rooms.—A new handsome Reading Case can be supplied at a nominal charge of 2s., by post 2s. 6d., on early application to the Publisher, 175 Strand, W.C.

SPECIAL NOTICE TO THE TRADE AND OTHERS.

[Extract from a lecture on Architects' Libraries by Professor T. Roger Smith, F.R.I.B.A., at University College, October 10, 1893.]

"Lastly, let me recommend the back volumes of the professional journals. In the course of years all sorts of architectural topics come up in the public press and before the professional societies, and if you hunt through the indexes of these publications when you are seeking for information which eludes you in books, you will often be rewarded."

There has been a considerable demand for the back numbers of *The Architect* during the last three or four months, which we have no doubt has arisen from the remarks made by Professor Roger Smith, as contained in the above quotation; but the consequence has been that our stock of back numbers is getting very low, and consequently, in future, the charge for back numbers of previous date to January 12, 1894, will be 6d. each.

A few of the back volumes may still be had, price 12s. each.

EDITORIAL NOTICES.

The authors of signed articles and papers read in public must necessarily be held responsible for their contents.

No communication can be inserted unless authenticated by the name and address of the writer—not in every case for publication, but as a guarantee of good faith.

Correspondents are requested as much as possible to make their communications brief. The space we can devote to Correspondence will not usually permit our inserting lengthy communications.

NOTICE TO ALL WHOM IT MAY CONCERN.

March 1, 1895.

MESSRS. W. & R. LEGGOTT, of Silens Works, Bradford, Yorkshire, and 226 High Holborn, London, W.C., have the sole right of making, manufacturing, or constructing Fanlight and Skylight Openers, known in the Trade as "Silens," or "Leggott's Openers," under their various Patents, all of which are unexpired and unimpeached and of full authority and effect.

The word "Silens" is cast on all their Silens Openers.

Any person who may be found infringing such Patents or making Fanlight or Skylight Openers protected by such Patents, or any of them, or selling or otherwise dealing in the same, will be proceeded against as may be advised.

TRADE NOTES.

WE give a list of buildings where Messrs. W. & R. Leggott, Silens Works, Bradford, and 226 High Holborn, London, have lately completed or are about to complete the work of fixing their fanlights and other gearing. They have also again succeeded in obtaining the contract for a term of years from the London School Board for the whole of the fanlight and other gearing in their schools. Brighton Public Baths, Buckingham Palace alterations, North-Western Fever Hospital, Hampstead; South-Eastern Fever Hospital, Old Kent Road, London; new disinfecter, Newington Vestry; London Hospital, Whitechapel; St. Luke's Union, administrative blocks, London; Fulham Union, administrative blocks; St. Olave's Grammar Schools, London Bridge; Ward's School, Thames Embankment, London; Guildhall School of Music, London; Goldsmiths' Institute, New Cross, London; Grocers' Company Hall, London; Bishops-gate Institute, London; Woolwich Public Baths; Bow Baths and Wash-houses, London; Barclay & Co.'s Bank, Cavendish

Square, London; Hong-Kong and Shanghai Banking Corporation, Lombard Street; Holloway's Sanatorium, Virginia Water; Reading Town Hall; Vaudeville Theatre, London; Reading Union; Tivoli Theatre, London; Public Library, Drury Lane; Central Hall, Holborn; New Admiralty Buildings; Drill Hall, S.T.H., Bow; Drill Hall, Bunhill Row, E.C.; Imperial Institute, Albert Gate; Hymers College, Hull; Aston Baths, Birmingham; Technical School, Gloucester; Cornwallis St. Baths, Liverpool; Soap Works, Port Sunlight; Dye Works, Apperley Bridge; New Baths, Farnworth, Lancashire; New Infirmary, Halifax; Yorkshire Penny Bank, Bradford; Craven Bank, Bradford; Lotherton Hall, near Saxton, Yorkshire; St. Ann's Church, Bishop Auckland, &c.

It may be of interest to note that the first hotel in Great Britain to adopt the use of electricity for driving elevators or lifts is the Clarendon Hotel, Edinburgh. In this hotel the Otis Elevator Company, Limited (late American Elevator Company), are just fitting an electric passenger and an electric service elevator. The list of hotels on the Continent already fitted with "Otis" electric elevators is a long one, and includes many of the well-known hotels in Paris and other cities. Now that the public has learned that the "Otis" electric elevator is not an experiment, but thoroughly reliable and efficient in every respect, and also remarkably economical in cost of working and repairs, it is being adopted rapidly, one of the company's latest orders being for twelve electric elevators in one building in Berlin.

THE new Board schools, Watford, are being warmed and ventilated throughout by means of Shorland's patent Manchester grates, the same being supplied by Messrs E. H. Shorland & Brother, of Manchester.

MR. G. STRAUS, of 130 Queen Victoria Street, writes as follows:—Having recently given up one of my agencies for incandescent lamps, I beg to inform you that this in no way interferes with my trade in this article. I still continue to sell the same lamp which I have been supplying for so long, and which has given universal satisfaction. I am happy to say my works have also decided to keep in future here a much larger and better assorted stock than hitherto, and which will enable me to execute all orders with the utmost promptitude. Every lamp is carefully tested before leaving the works, and as an additional precaution I have made arrangements, at considerable expense, to have every lamp retested before leaving my warehouse.

ELECTRICAL.

MESSRS. CROMPTON & CO., of 148 Brompton Road, have recently carried out the electrical heating of the Vaudeville Theatre. At first it was contemplated to use a system of hot-water heating, but, after carefully considering the matter, the management decided that electrical heaters afforded a more advantageous system. Twenty-two "box" or wall radiators and four large portable radiators, all of the Crompton-Dowsing type, are employed, and they answer the purpose admirably. The temperature of the theatre is maintained at 60 deg., while the corridors may be as low as 40 deg. The heating arrangements are under absolute control, and any portion may be turned off or on at will. The electricity used is taken from the Charing Cross and Strand Electricity Supply circuits and charged at 4d. per unit, and when all the apparatus is at work 9 units are consumed per hour. With electric radiators there is no danger of fire, as there is no combustion, and the temperature is about the same as that of hot-water pipes. The electrical cables are of Henley's highest quality, switches, cut-outs, safety connectors, &c., of the best, and Messrs. Crompton endeavour to make this pioneer installation complete in every respect. Some difficulty was at first experienced with regard to the fire office and London County Council, as no rules were in existence which covered the case; but all the authorities appear now to be convinced that electric heating, when properly installed, is very safe, and perfectly suitable for public buildings. It is stated that electric radiators are often used in an auxiliary sense where sufficient heat is not obtainable in buildings heated by hot water. They are also useful for chilly evenings, and at times when it is not cold enough to work the whole system of heating, but a little warmth is required in any particular room or portion of a room.

OUR HEALTH IN WINTER.—Dr. Andrew Wilson, writing in *Lloyd's Newspaper* on diet, says: "The teaching of nature should never be neglected, and in the matter of winter food let us see we are not wrong, and take sufficient fat, for the changes that result in the wear and tear of our bodies are lessened in intensity by the fat of food, and the need for flesh is always less when fat forms a due proportion of our diet." The Doctor proceeds to enumerate natural products that are admirable, among them "Cocoa" with its contained Cocoa Butter. Relatively to this it may be said that EPPS'S PREPARED COCOA retains all the constituents of the natural Cocoa, including the oil or butter, intact.—ADVT.

VARIETIES.

WE have received a copy of their new "Empire Series" from Messrs. Marion & Co., which by special permission has been dedicated to Her Majesty Queen Victoria. It contains sixteen views (10 inches by 8 inches) of Windsor Castle from photographs taken expressly for the purpose by Mr. Horatio Nelson King. One most commendable feature of the publication is that each one of the series will form an album complete in itself, and not a hotch-potch of pretty things from here, there and everywhere. The series will comprise two sections, devoted respectively to eminent personages and historical buildings and places of the Empire. Valuable letterpress accompanies the illustrations by a competent writer. The illustrations show the Castle itself, also the east terrace and the east and south fronts. Theed's statues of the Queen and Prince Albert, the Throne Room, Vandyck Room, Grand Reception Room, Waterloo Chamber, Tapestry Room, Oak Room, Grand Corridor, Green Drawing Room, St. George's Hall, Albert Memorial Chapel and choir of St. George's Chapel.

THE *Irish Times* says:—The Grand Jury of the county of Cork have appointed a committee to inquire into the condition of the sea wall at Youghal and the danger to county roads likely to be affected by the breaking in of the sea, and the value of the property likely to be inundated, and to draw up a report for the information of the Grand Jury at the Summer Assizes. Since the report of the engineer of the Great Southern and Western Railway Company had been laid before the Grand Jury the sea had encroached considerably, and that unless some action was taken by landowners and the public before next winter, the whole district would be inundated by the sea.

At the meeting of the Edinburgh Association of Science and Arts Mr. Wm. Hume gave an address on "Photographic Colour Printing."

At the meeting of the Birmingham City Council on Tuesday the technical school committee were authorised to spend a sum of 6,080l. for providing an electric lighting installation at the new technical school.

THE Morecambe District Council have applied for a loan of 5,436l. for private street improvements, and an inquiry has been held.

THE Royal Scottish Academy, Sir George Reid, P.R.S.A., presiding, have agreed that for this year no new election of Associates should be made.

THE CHARING CROSS BANK.

THIS bank has been established nearly a quarter of a century, and with every year has increased its business. It is conducted on the same lines as the large joint-stock banks, but it will take deposits as low as 10%. Money can be borrowed at a reasonable rate of interest in sums ranging from 30% to 2,000%, and any suitable security is accepted, advances even being

PASSENGER LIFTS.

At the ordinary meeting of the Civil and Mechanical Engineers' Society a paper on the subject of "Passenger Lifts" was read by Mr. S. A. Court, vice-president. Having referred to the earlier forms of passenger lifts in use in England, the author gave details of various improvements lately introduced, such as the variable power hydraulic and the electrical systems, and

CHARING CROSS BANK: INTERIOR.

made on furniture. The interests of the bank and of their clients are safeguarded, and the latter are not subject to extortion. The prospectus can be obtained of the manager, Mr. A. Williams, Charing Cross Bank, 28 Bedford Street, Strand, W.C.

"HALF AN HOUR" in a gold mine is one of the new features represented at the Royal Aquarium, Westminster—a representation of the Saratoga Mine in the Rocky Mountains, Colorado.

gave figures to support his view that the latter has already shown by practical working that at even present prices the electric lift is a serious competitor with the hydraulic lift.

Safety appliances and possible causes of accidents were then detailed, and mention was made of the recent fatal accident in the City. The author estimated that on an average fully 90 millions of passengers are carried annually in London alone, and pointed out that the percentage of accidents is extremely small.

ART PLATES FROM "THE ARCHITECT."

Awarded Gold Medals, International Health Exhibition and Architectural and Building Trades Exhibition (1889).

PROOFS on PLATE PAPER of the following Illustrations which have appeared in "THE ARCHITECT" can now be obtained in a separate form suitable for Framing.

THE MARTYRDOM OF ST. STEPHEN. By E. J. POYNTER, R.A. Size, Forty Inches by Fifteen Inches. Price One Shilling. Free by post, carefully packed inside patent roller, One Shilling and Three Pence.

"AND THE SEA GAVE UP THE DEAD." By Sir FREDERIC LEIGHTON, President of the Royal Academy. A few Proofs of this Fine Art Plate can be obtained (if ordered at once), price Two Shillings each. Free by post, carefully packed inside patent roller, Two Shillings and Two Pence.

THE BANQUET. The well-known and beautiful Chromo-Lithograph by H. STACY MARKS, R.A. Size, Thirty-nine Inches by Fifteen Inches. Price One Shilling. Free by post, carefully packed inside patent roller, One Shilling and Three Pence.

1. AN OFFERING TO CERES. 2. THE EDUCATION OF BACCHUS. 3. MINERVA VISITING THE MUSES. 4. JUDGMENT OF MIDAS. By W. HAMILTON. Size of each plate, Forty Inches by Fifteen Inches. The whole forming a very beautiful Frieze in Bartolozzi Mezzotint. Price per set, Six Shillings on Proof Plate. Free by post, carefully packed inside patent roller, Six Shillings and Six Pence.

THE HISTORY OF JOAN OF ARC. By M. JULES EUGENE LENEPVEU. From the Wall Painting in the Panthéon, Paris. Four Pictures on one Plate. 1. Domremi: Inspiration. 2. Orleans: Struggle. 3. Reims: Triumph. 4. Rouen: Martyrdom. Size, Forty Inches by Fifteen Inches, on Proof Plate. Price, Two Shillings. Free by post, carefully packed inside patent roller, Two Shillings and Six Pence.

THE WATERLOO HEROES. By J. P. KNIGHT, R.A. Dedicated, by Special Permission, to VISCOUNT WOLSELEY, K.P., G.C.B. Proofs, price One Shilling each (thin Plate Paper). Proofs (Special), price Two Shillings and Six Pence each (thick Plate Paper). Size Twenty Inches by Thirty-six Inches. Framed and Glazed in Oak, Complete, One Inch, Twelve Shillings each. Ditto, One and a Quarter Inch, Fourteen Shillings each. Ditto, One and a Half Inch, Seventeen Shillings each.

THE TOILERS OF THE DEEP. Two Tinted Ink Photographs. Size, Eighteen and a Half Inches by Thirteen and a Half Inches. Price Two Shillings. Free by post, carefully packed inside patent roller, Two Shillings and Three Pence.

JOHN SELL COTMAN'S PICTURES, lately on Exhibition at the Burlington Fine Arts Club. The Plates are uniform in size, Twenty-one Inches by Fifteen Inches. The Titles are as follows:—1. Rouen from Mount St. Catherine. 2. Breaking the Clod. 3. View in North Wales. 4. Norman Arches. 5. Byland Abbey. 6. Norwich, from the Cromer Road. 7. Dewy Eve. 8. Mousehold Heath. 9. Cader Idris. 10. Castle Eden Dean, Durham. 11. Bamborough Castle. 12. The Interior of Norwich Cathedral. 13. Mountain Pass in the Tyrol. 14. Postwick Grove.

The price of the Set is Twelve Shillings and Six Pence; by post, carefully packed in patent roller, Thirteen Shillings. Kindly order early, as only a limited number of proof copies can be obtained.

May be obtained from all Newsagents, Booksellers, Messrs. W. H. SMITH & SON'S Bookstalls, or from the Publisher, P. A. GILBERT WOOD, 175 Strand, London, W.C.

THE BUILDING EXHIBITION.

THE Building Exhibition, to be held at the Royal Agricultural Hall, Islington, regarding the arrangements of which we have from time to time alluded, will open on Monday, the 26th inst., and we are able to supply the following particulars referring to the proposed exhibits of sundry prominent firms.

Ellis, Partridge & Co.

The Stand of Messrs. Ellis, Partridge & Co., of Grey Friars, Leicester, must be personally inspected to appreciate the goods, as we can only call attention to the various wares by their simple names. The exhibit will consist of "Redbank" red-pressed facings, also moulded and ornamental bricks in great variety for arches, cornices, strings, door and window-jambes, floor-bricks, panel-borders, air-bricks, terra-cotta in various forms, a large entablature bearing date 1895. These bricks are now used in all parts of the country, and the firm are now supplying them for county council buildings, technical schools, electric-lighting stations, public libraries, Board schools, &c. The Stand of Messrs. Ellis, Partridge & Co. will be a new feature, being specially made to display their exhibit, in varnished wood and navy blue cloth. Messrs. Ellis, Partridge & Co. have, we find, much increased their output during the past year, and their works are lighted by electricity.

Stanley Brothers,

of Nuneaton, show their excellent manufactures at Stand No. 163, Row A—glazed bricks and tiles, blue bricks, coping, &c., red, buff and blue quarries, red and brown roof tiles, red ridges and finials, red and buff chimney-pots, ornamental red terra-cotta; and at Stand No. 217, brick, tile, sink and gully-trap presses. Stanley Bros. are known for their excellent building, paving, stable bricks, &c., not to mention that they

supply all that is wanted in the way of ornamental tilework for all purposes, garden requirements and such like included.

S. & E. Collier.

Messrs. S. & E. Collier, of the Brick, Tile and Pottery Works, Reading, provide a very interesting exhibit for architects, builders, &c., in the samples they show of their excellent specialties. A principal feature of the exhibit will be their red roofing tiles, machine and hand-made, with specialties for insuring their vegetating, and others that will keep their colour. Also red ridges of all kinds, intersecting tiles, finials, terminals, terra-cotta for building construction, mural tiles, air bricks, panels, &c., which, we should mention, Messrs. S. & E. Collier make a special feature of in their manufactures. In this case, also, we must advise our readers to personally inspect this exhibit, as we cannot do proper justice to it in a bare recital of what is shown. In addition, we would call attention to the splendid colour of red that characterises the above-mentioned wares.

H. J. & C. Major, Limited.

The prominent features of this exhibit will be Messrs. Major's patent weatherproof roofing tiles of two or three patterns, notably their improved patent double Roman pattern showing a hip, and also their patent interlocking Broseley plain tiles, having a hip and valley. Both kinds of tiles will be laid on small but suitable specimen roofs exactly as they are used on buildings either large or small, except that the pitch of the roof may be higher or lower, as designed. These tiles are simply laid on the battens by lugs or nibs, and do not require the aid of nails to fix them, nor bedding in mortar or cement to keep out rain or snow, while there is sufficient ventilation to prevent decay of roof timber. They therefore offer many advantages over ordinary tiling, inasmuch as there is less weight on the roof when completed, and security against rain, snow and wind stripping. At the same time a tile may be removed and replaced as firmly as at first. It may also be stated that the design of these tiles includes great strength, and a roof covered with the patent Romans or patent Broseley tiles is not liable to the excessive damage caused by breakage by pressure of ladders placed against them and workmen moving about on them. The economy effected by using the tiles in question includes somewhat less timber, saving of nails and material for bedding, more expeditious work, and therefore reduced working expenses. Briefly, a sound roof is secured at a minimum cost.

HILL'S WHEEL-BOLT MORTICE LOCKS

En suite with Master-Key Arrangement,
FOR HOTELS, HOSPITALS, ASYLUMS, &c.

PATENT REVERSIBLE RIM LOCKS, IN IRON [OR BRASS, DRAWBACK LOCKS,
NIGHT LATCHES, &c.

JAMES HILL & CO., 100A QUEEN VICTORIA STREET, LONDON, E.C.

John Grundy.

As usual Mr. John Grundy will be represented. His specialties are so well known, apart from his name invariably appearing at exhibitions, that no large display is required. His patent church-warming apparatus is well known to all our readers. He will show some patent fire-grates, one at work, that when in action will keep lighted for seventy hours without any attention given to it, the cost of the fuel being about 3d. to 4d. No better fire-grates than these can be expected to be on exhibition. After the experience of this winter many will be glad to examine them and make a memorandum for present or future needs.

Gibbs Brothers,

of Charnwood Works, Loughborough, are manufacturers of red and white facing bricks, made from the well-known Leicester-shire clays, hard, durable and of excellent colour and quality, which are to be on view; also their superior sand-faced bricks for villas and country houses, enriched mouldings, terra-cotta string-courses, bases, corbels, diapers, panels and every description of ornamental moulded bricks to any design. Their white bricks are specially suited for internal work for churches, and for colour and durability cannot be surpassed; also plain and ornamental red ridges, finials, keystones, arch bricks and ventilators, red and buff quarries and floor bricks, chimney tops, &c. Owing to the extremely severe weather of the present year Messrs Gibbs Bros. were unable to make any specialties in bricks or terra-cotta for the exhibition, and the whole of their exhibit has been selected from their ordinary stock. Their red facing bricks are now being used on the new hospital at Shooter's Hill, Woolwich, for the London County Council, and give every satisfaction. Having recently erected new works and put down some of the latest machinery, they are in a position to execute all orders with care and despatch.

L. V. Riley & Co.

Messrs. L. V. Riley & Co., engineers and electricians, 10 Throgmorton Avenue, E.C., are among the exhibitors. Their exhibit at the exhibition will consist of brass, copper and iron-work in new designs for electric fittings, and they have opened a new department in that particular branch. Messrs. Riley & Co. have a reputation not only as engineers and electricians, electric-lighting contractors, &c., but as art metal workers, contractors for country house and mansion installations, electric-lighting specialties, bell, telephone and motor work. In this

new departure for use of electricity as an illuminant there is a special call for artistic fittings at a moderate price. The exhibit will show that these conditions can be complied with.

Incandescent Gas Light Co., Limited.

The new Welsbach system of lighting, by the Incandescent Gas Light Co., Limited, of Westminster, has in the last few years made rapid strides in public favour, and has come into very universal use. We have more than once described the system and explained the technical details and the process of manufacturing the filaments or mantles, in the use of which the secret of success in this system of lighting depends. In using this system an atmospheric gas-flame is produced, also the noxious effects of gas, smokiness, &c., are eliminated. For a serviceable light it cannot be excelled. Electric light does not, we think, surpass it, and the general favour it has found is a good credential. The light is also particularly adapted for an able designer to produce artistic drawings for the production of ornamental glass shades in every variety for the gasaliers.

Kauri Timber Company.

This company has acquired twenty-eight timber mills in the northern part of the North Island of New Zealand. For over a quarter of a century it has been the idea to make known at this side of the world the value of the Kauri pine, which seems exclusively confined to New Zealand. The company state that it grows to a height of 150 feet—that no doubt is the average, though they can be seen 200 feet in height, straight, like a ship's spar, without branching out, till more than 100 feet high. The girth of the pines is enormous in many cases. It is impregnated with a gummy substance, and is practically indestructible by damp. Planed up and varnished it is most valuable for panelling or cabinet-work, and no one who looks at the samples to be shown by the Kauri Company can wish for a more beautiful wood. The company are introducing it for every purpose that wood is employed for. In addition it is to be supplied in wood blocks for paving carriage-ways. It may seem an ignominious use to which to put such beautiful wood, but there is no doubt that no wood carriage-paving could stand half the wear and tear of the Kauri wood, owing to its antiseptic qualities.

Charles Erith & Co.

Messrs. Charles Erith & Co., heating, ventilating and drying engineers, occupy Stand 120A, Row D., where all par-

OPEN TOP, AS SHOWN, OR VENTILATING. PLAIN OR ORNAMENTAL.

Much used in Places of Worship, Lecture Halls, Board Schools, Shops, Large Offices, Markets, &c. Suitable for wherever a Very Powerful, Well Diffused, Soft, Economical, and Easily Managed Gas Light is desirable. Made in Five Sizes.

HONoured WITH SUNDRY IMITATIONS.

Seven years from Invention up to April 1890 over 11,300 sent out. But

Up to the end of 1893, over 23,000 sent out.

A PERPLEXED GAS INSPECTOR.

"There has been so great a reduction in our consumption of gas at Speke Hall, Battersea, since we had your CLAPTON LIGHTS, that the Gas Company declared our meter must be out of order. They have had it examined, and can find nothing wrong."

R. H., London, September, 1893."

The Gas Light also at this Hall is said to be over twice what it was before.

J. C. HALLIDAY,
INVENTOR AND MANUFACTURER.

12 GRAINGER STREET,
NEWCASTLE-ON-TYNE.

A LIST of ART PLATES published in "THE ARCHITECT" will be forwarded on application to P. A. GILBERT WOOD, Publisher, 175 Strand.

particulars and information in regard to their excellent appliances may be got by visitors. All machines which are too large to exhibit will be shown by photographs, plans, &c., and their uses demonstrated. They can be seen in operation where they are in actual use, we understand, by any visitors who make application for that purpose. The machines include hot blast mechanical heating and ventilating apparatus, as used for factories, schools, churches, theatres and large buildings generally; indirect steam heating combined with positive ventilation on "Plenum" principles. Erith's timber-seasoning system; hot-air methods, under perfect regulation as regards volume of air, temperature, humidity, &c. Erith's economical brick-drying system; hot-air methods, with Cummer's patent hot-air furnace methods; these dry 20,000 plastic bricks with one ton of small coal; labour and handling generally saved by the use of trucks. The "Cummer" patent automatic drying and calcining machine, is largely used for drying and preparing clay for dry grinding; the only economical and successful method of drying clay artificially; all kinds of materials, from chemicals and minerals to wet grains and refuse can be most economically and successfully dried in modified styles of the "Cummer" drying machine. The "Simpson" brick press, the leading American machine, is of perfect construction, resulting in large output of the finest possible bricks, while using very little steam, also the "Simpson" apparatus for steaming and softening shales, &c. Circulars may be obtained at the Stand which will prove very useful for future reference by those who inspect this exhibit. The great advantage of this system of warming and ventilation of Messrs. Charles Erith & Co. is its efficiency, with freedom from complication of apparatus. Natural means have been relied on to devise a simple system to secure the purpose in the most effectual way at a small outlay. In wintry weather the question of warmth is necessarily uppermost, but in periods of summer heat the public only long to have a supply of cool air in their houses, which is supplied by this system.

Robert Adams.

At the stand of the Adams Building Trades' Emporium, 67 Newington Causeway, S.E., are shown Robert Adams's widely known and used door springs, ventilating apparatus casement bolts, "Victor" stays, sash fasteners, &c., as under:—The "Crown Victor" door spring for silently closing swing doors. These springs are most compactly designed, and admit of ready fixing in any position. The hydraulic check is certain in action, and the power of the spring can be regulated

to suit any requirement, whilst the working parts are so arranged as to offer a minimum of friction, so enhancing the durability of these goods. The "London Victor" is designed for silently closing single-action doors, and embodying all the features of the "Crown Victor," and strongly recommended for all classes of work, particularly where reliable springs are necessary. The "Empress Victor" is a pneumatic and overhead check spring, which is very neat in appearance, and the fittings are very strong, being made in malleable iron, and will admit of the door being opened wider than any other overhead spring. The "Combination" is a spring designed for closing the door silently into the frame, and allows it to be set open at any desired angle, so dispensing with the unsatisfactory leather straps and lance wood springs. The "Folding Stay" fanlight openers are recommended for neatness and efficiency and easy action. Another well-known pattern is the "Link Motion," which also works by means of screw rod and regulator. The ratchet fanlight adjustment is useful for small fanlights, working with cord or long arm; is cheap, neat and strong. Among other patterns may be mentioned the "Scott" and "Twin Screw," working with cord or rod arrangement, among the recent being a series of openers which are now being worked out, actuated by stiff back chain, and worked either by cord or rod. The screw rod and regulator action for securely controlling long ranges of light are also shown, and the same also adapted for opening and closing skylights in any position. Samples representing the well-known bolts called the triple action, weather-proof tongue, thrust action, espagnolette, &c, "Triumph" sash fasteners, and "Victor" casement stays are shown.

Arthur W. Adams

exhibits his new patents, the "Impervious" metal casements and frames as follows:—No. A1 section, guaranteed weather-proof, suitable alike for opening inwards or outwards, singly or in pairs, hinged at sides, top or bottom or on pivots, and fits jambs of any material or detail. The section being moulded is neat, at the same time is simple, strong, and very rigid. There are four weather stops and three spaces, and a channel with ducts to collect and pass away any interior surface moisture. Accuracy of work, &c., is ensured by improved methods in making. The repeated orders executed for this section already proves how much this invention is appreciated. The "Impregnable" automatic bolts for metal casements supersede the common slide pattern, being neater, more efficient, and self-

locking. The "Impregnable" front door bolts, with automatic lever-locking action, give the greatest security, combining in one case the functions of a night latch, hall door lock and tower, or barrel bolts. The lever combination is unpickable and forcible, and absolutely reliable. The "Impregnable" locking bolts are also made to suit all casements and other doors, gates, &c. The "Exodus" panic door fittings, of guaranteed reliability for safety and security, approved and passed by the London County Council, and greatly admired for their perfect and easy action and attractive appearance, may also be used to serve for entrance, but cannot be picked or forced from the outside, nor can the interior safety use be interfered with.

John Lewis.

Mr. Joseph Lewis, of 5 and 6 Great Winchester Street, E.C., shows at his stand lightning conductors and their several fittings and fixings, and important improvements therein, notably his patent "Lewis Link" coupling, which is the only device made in a single piece for connecting the upper terminal of lightning conductors to the copper tape. The advantages of this simple arrangement are many and obvious upon examination of this coupling as exhibited in sections at this stand. This coupling was awarded a prize medal at the great Electrical Exhibition, Crystal Palace, 1892. In addition are shown specimens of solid high conductivity copper tape, copper rope, &c. It affords a larger area of surfaces in permanent contact than is possible in any other device for a similar purpose. An improved electric bell which cannot fail to ring in hot, cold, damp or dry atmospheres; any number of bells may be rung in any part of a building by single wiring from one push. A model to scale of a lofty chimney, showing the method adopted for altering, repairing, pointing or banding shafts and steeples without the expense of scaffolding, and without stopping the working of the shaft.

John Tann.

Mr. John Tann, lock and safe engineer, shows his new pattern party-wall doors. The special feature of these doors is an angle iron stile on door instead of the ordinary flat stile, the advantage being that it adds greatly to the rigidity of the door and prevents it warping, a great consideration in event of fire; the prices are also much lower than that charged for the usual

panelled doors. The new pattern fire-resisting warehouse doors are designed for heavy risks of fire, the back of the door is fitted with a 4-inch chamber filled with steam generating fire-resisting composition. An ingenious bolting arrangement is fitted which ensures the door being fastened, as only one movement is required to throw a bolt at top, bottom and front. In face of the failure of so many doors in recent great fires this is just the thing that is wanted, and should command a ready sale, the prices being moderate. Next come ordinary panelled party-wall doors and a first rate well-finished plate closet door for butler's pantries. Following these are strong room doors of various prices and qualities, and lastly, a very fine specimen of a fire and burglar-proof banker's bullion room door weighing 2 tons, complete with steel vestibule and ventilating grille. There is also a good show of safes from a neat five-guinea safe for dwelling-house purposes to the elaborate burglar and drill-proof diamond merchant's safe. Locks of all descriptions are also shown. This business was established in 1795, and the firm just enters into its second century, and is the oldest safe manufacturing firm in the world. The position is unique that in over one hundred years the business has been in the hands of only two generations, the business having been founded by the father of the present Mr. Tann, who entered the factory in the early thirties, when cast-iron chests were mostly in use, and a few wrought-iron safes with an inner lining, forming only an air chamber. Since then what alterations have been made in the manufacture of safes at the works where, one hundred years ago, the firm were making cast-iron chests about $\frac{1}{4}$ inch thick, weighing only a few hundredweight? And now they are making safes 3 inches thick of combined steel and iron, and a single safe weighing 7 and 8 tons each, with chambers 4 to 6 inches thick, filled with the latest invented steam-generating, fire-resisting composition.

The Vitreous Enamelled Glass and Tile Company.

This company (office and works, 19 Goulton Road, Lower Clapton, N.E., Stand No 21, Row A) exhibit a number of panels of glass decorated in various styles—floral, ornamental, heraldic, ecclesiastical, &c.—in their vitreous enamel, and by the judicious use of gold, which is fused into the glass at the same time as the enamel, gain a remarkably brilliant effect. The advantage of this style of decoration with its freedom of treatment gives not only a brilliant colouration, but by artificial light shows as well as by daylight, and in some cases even better. A maximum of light is obtained by the decoration being on white glass, though the effect on coloured glass is

very good. For fascia work we fancy it will have a peculiarly good effect, as seen in the name over their stall; we also notice the City Arms as a specimen of heraldry. It seems to work up well for the Japanese and Chinese styles, and some of the scroll patterns with gold for door panels, fanlights, &c., point to it as a coming style. The lettering also is very good, and if, as we understand, the prices are not at all out of the way, we see no reason why an innovation in glass decoration having permanency should not make good headway.

Hermann & Co.

We were recently greatly interested in inspecting some very ingenious wood-carving machines patented by Messrs. H. Hermann & Co., of Dod Street, Limehouse, and some panels turned out by them for exhibition at the forthcoming Builders' Show at Islington. The carving, which is mainly, almost entirely, in fact, executed by the machines, is, however, carefully hand-finished, and possesses all the crispness and delicacy of the best handwork, than which it is of course immensely less expensive. It is eminently adapted to all purposes to which the latter could be applied, as well as to many where its cost would be prohibitive, as house and room doors, dados, mantelpieces, shutter-boxes, ship and railway saloons, offices, refreshment buffets, &c., as well as to cabinetwork and especially piano fronts and backs. The machines execute with equal facility the boldest and the most delicate designs; nor is intricacy any obstacle, and while Messrs. Hermann & Co. have a selection of some hundreds of patterns in stock, they are prepared to work with accuracy to their customers' drawings. Although Messrs. Hermann & Co. have only recently added this branch to their already extensive business, the firm has been established since 1877 as timber merchants (and importers) and furniture manufacturers, their chief manufacture being bedroom furniture. It is one of the largest firms of its kind in Europe. They employ nearly 500 hands, and the factory covers an area of over 56,000 square feet. They have every facility of waterway for conveyance of timber from the docks. Their plant and machinery are of the newest construction, and embrace all the latest improvements, including an electrical plant, amongst which is an electric crane which is used for lifting timber from the barges on the adjacent canal. They also have a branch at Evansville (Indiana, U.S.A.), the factory, saw mills, drying house, and timber yards of which cover an area of about 12 acres. The drying house has a capacity of 1,000,000 feet.

THE WEATHERING OF BUILDING STONE.*

THE slow decay of everything exposed to the weather has become a proverb, and from the earliest times men have moralised on the "gnawing tooth of time," as though time were some relentless monster devouring slowly man and all his products; but of late years geologists have begun to make some inquiries as to the monster, and to find out somewhat exactly what time's gnawing tooth really is. The question is one of great importance to the student of geology, for the weathering and wearing away of the solid rock and the building up of its materials in new places are among the most significant factors in the ceaseless round of change by which mountains and valleys and plains are carved and remodelled on the earth's surface. To the geologist no structure is permanent, the "everlasting hills" do not last for ever; in fact, the destructive forces are most actively at work where the mountain lifts its head so boldly, as if to defy the elements.

The "tooth of time," when examined a little carefully, turns out, as so many bugbears do, to consist of very simple and innocent elements. Air, water, change of temperature—these three factors alone, or in combination, with traces of a few common acids, are the effective forces in the weathering of the rocks of the geologist and of the stone of the architect. The effects produced by these agencies may be purely mechanical or purely chemical, or more often a mixture of both.

In climates like our own, where the extremes of heat and cold may run from 100 deg. in summer to 15 deg. or 20 deg. below zero in winter, the effect of mere change of temperature may be important in its disintegrating action on building stone. The rise of temperature when sunshine falls upon the wall of a building is imparted to the outer layers of particles of the blocks of building stone and expands them, granite having been found to expand '000004825 inch per foot for each degree Fahrenheit, marble '000005668, sandstone '000009532.

Since stone is a poor conductor of heat, the surface will expand more rapidly than the interior, and there will be a tendency to form minute cracks and to chip off the surface of the stone. It is said that the south side of stone buildings, exposed to great changes by the coming and going of sunshine, begins to roughen and disintegrate sooner than the north side

in New York and other American cities. The ill effects of change of temperature will, of course, be more apparent in the case of stone like granite, made up of minerals differing in their rate of expansion by heat. This is most strikingly shown in case of fire, when granite, though stronger and more compact than sandstone or limestone under ordinary circumstances, crumbles far more easily in the intense heat.

Another injurious effect of change of temperature is to be found in the loosening of the joints between the blocks of stone in a building. Supposing the stone to have been laid in summer, all the blocks will occupy less space in the cold of winter, and minute fissures will tend to form in the cement or between it and the stone. These fissures admit water and make the starting-point for other changes.

Change of temperature alone is, however, not a rapid agent in disintegration. It is the presence of water that gives it efficiency as a destroyer in climates like ours in winter, where freezing and thawing occur in rapid succession. When water freezes it expands with an almost irresistible force, which has been estimated at 138 tons per square foot at 2 deg. below freezing, and is quite sufficient to rend the strongest rock. All the tiny fissures and crevices of a block of building stone exposed to rain or melting snow become filled with water, which may afterwards freeze, wedging off fragments. Another thaw, followed by another frost, pushes the parts still farther asunder, until the stone splits and crumbles. Stone buildings of many kinds illustrate this action on the sides exposed to storms. It is very well seen on many New York brown stone houses, where the porous Connecticut sandstone has been sawn and set on its edge, and after a few years scales so as to be quite unsightly.

The action of frost depends very largely on the porosity of any stone exposed to its influence. A compact massive stone like granite or many limestones is little affected, while porous limestones and especially sandstones are very quickly injured in exposed positions. In this respect the capacity of a stone to absorb water is of great importance, and one may say with Sterry Hunt that, other things being equal, "the value of a stone for building purposes is inversely as its porosity or absorbing power." N. H. Winchell gives in a report of the "Geological and Natural History of Michigan" (vol i. p. 197, &c.) a table showing that massive crystalline stones, like granites, syenites and gabbros, absorb very little water, generally much less than 1 per cent.; dolomites absorb a little more, and dolomitic limestones still more, up to 3 or 4 per

cent. Limestones absorb rather less, while sandstones absorb very much more, the lowest amount in his table being 3 per cent., and the highest 12·69 per cent. Sterry Hunt found that Potsdam sandstones from Canada absorbed from 0·50 to 3·26 per cent., Medina sandstones from Canada 3·31 to 4·04 per cent., and subcarboniferous sandstone from Ohio 9·59 to 10·22 per cent. Silurian limestones and dolomites from Canada examined by him absorbed from 0·11 to 5·55, while tertiary limestones from Caen, France, absorbed from 15 to 16·05 per cent. of moisture.

As a general rule a stone absorbing 10 per cent. of water crumbles rapidly in our winters, and should not be employed where carving or a fine finish of any kind is exposed to the weather.

Thus far the purely mechanical side of weathering has been discussed. Let us now turn to the chemical side. The air consists of about 4 parts of nitrogen and 1 of oxygen, with varying amounts of watery vapour, a little carbonic acid and traces of ammonia and other nitrogen compounds. In cities it may also carry soot and traces of some common chemical compounds, such as sulphur dioxide, sulphurous and sulphuric acids, hydrochloric acid, nitrous and nitric acids.

Rain water is more or less strongly charged with oxygen, carbonic acid and other substances found in the air. The nitrogen of the air is inert and the oxygen and other substances are active only in the presence of water, so that very dry air has little or no effect in weathering. In very dry climates like that of Egypt monuments of stone may be ground off by driving desert sand acting as a sand blast, but are scarcely affected in other respects after 4,000 or 6,000 years' exposure to the weather. How differently a damp climate affects the same stone may be seen only too well in the Egyptian obelisks transported to London, Paris and New York. It is well known that in the last city the granite scaled so rapidly that the obelisk had to be coated with paraffin to preserve it at all.

(To be concluded.)

At the meeting of the Northern Architectural Association last week, Mr. J. Oswald, president, in the chair, Mr. J. M. Moncrieff read a paper entitled "Theoretical and Practical Notes on Beams, Columns and Roof Trusses."

PARLIAMENTARY PROCEDURE AS AFFECTING
LIGHT RAILWAYS AND TRAMWAYS.*

ENGINEERING enterprise in Great Britain is at present checked by the methods and cost of Parliamentary procedure, departmental restrictions and local opposition. It is desirable that every means of removing any existing unnecessary restriction upon engineering enterprise should be carefully considered; and it is incumbent upon the engineer to show in what way Parliamentary procedure and departmental restrictions, enforced by Parliament, may be modified to public advantage.

It is a matter of common knowledge and remark that while on the one hand the cost of transport and communication in Great Britain are in all cases high, in many cases almost prohibitory to some of the industries, and in nearly all cases greater than the cost of transport on the Continent, capital is not attracted by projects, however good, for the provision of cheaper means of transit even for districts where no facilities now exist. Capital seeks employment on moderate terms of remuneration, and cannot find it. Engineers see the necessity for improved and cheaper means of communication and transport, and are able to show how to provide it at an expenditure which may be profitably incurred. But however good the project capital is not attracted. Why? Chiefly because of the prohibitory burden which is placed upon almost every enterprise by the cost of Parliamentary procedure and by the restrictions which have to be enforced by the Board of Trade in conformity with its limited powers.

There are few countries in the world wherein it is more necessary to provide for cheap intercommunication between the great main roads, and cheap transit upon them, than in Great Britain, and there are none in which the constructive work could be more cheaply carried out. There is no country in which the necessary capital is more available than it is in Great Britain, yet there is no country in the world in which so little is being done, or in which so little progress is made towards cheap industrial intercommunication by means of light railways and tramroads. The reason is that under existing laws and Parliamentary procedure, and in consequence of the abuses connected with the latter, the cost of obtaining permission to provide the much required facilities makes it impossible to provide them profitably.

* A paper by W. Worby Beaumont and Stephen Sellon, read at the meeting of the Society of Engineers on March 4, 1895.

The authors propose to confine their consideration of Parliamentary procedure more particularly to those questions which affect tramways, tramroads and light railways, although in [almost all branches of engineering the same procedure is necessary and the same criticism applies.

Notwithstanding the Railways Construction Facilities Act of 1864, which might be termed the Railways (Opposition) Facilities Act, and the Tramways Act, 1870, cheap legislation as affecting those branches of engineering is almost as impossible as ever, and as regards the Railways Construction Facilities Act, 1864, not one light railway has been constructed under it. Municipalisation is one of the results of this costly procedure, as it affords some limitation to certain forms of vexatious opposition and interference, but the spread of municipalisation is very far from being an unmixed good and against it some very serious objections are urged.

All interested in the branches of engineering to which the authors have referred are familiar with the various steps in the procedure under the 1870 Tramway and other Acts, and in this paper it is therefore assumed that it is unnecessary to dwell upon this part of the subject. Some of the elementary points in the proceedings have, however, in their order, to be touched upon with a view to suggestions.

Advertisements.—As one of the first steps in promotion, it is necessary to occupy large spaces in local and other papers, setting forth in the form of an advertisement an abstract of the whole of that which is completely set forth in any tramway or other Bill. Even for smaller projects this may occupy three columns of a newspaper. Now, the whole of that which is really required in the interests of the public could be equally well set forth in a short announcement as to the name, nature and extent of the project and the names of those from whom a copy of the Bill might be obtained at the cost of 1s. The unnecessary expenditure with which, under present procedure, every tramway project is burdened, is in the case of tramways further increased by the regulation which requires that after the Board of Trade has approved the draft Order, the same shall be printed in full as an advertisement in the local newspapers. A regulation of the Board further adds to the expense by encouraging the ingenuity of some newspaper publishers in finding reasons which prevent their publishing at the required date the Bill or Order after Board of Trade approval—reasons which are said to be absolutely unsurmountable, although always evaded by the payment of extra special rates. This is the result of the rule requiring that

“OPTIMUS” IMPROVED PHOTOGRAPHIC OUTFITS.

EXTRA LONG FOCUS.

British Journal of Photography says:—“The present model Rayment Camera is among the very lightest of actually rigid cameras offered to the public. The rapidity of opening and closing is greatly facilitated by the additional arrangement for throwing the pinion out of gear from the rack. There is no curtailment of view when lenses of short focus and wide angular aperture are in use. All movements necessary to the modern scientific photographer are included in this compact instrument.”

the second announcement shall appear in subsequent issues of the same papers as the first. These announcements have really little, if any, value; no one reads them for amusement, and those who for business reasons have to read such dry matter resort to a copy of the Bill or Order. The cost of this very extensive advertising has often imposed very heavy strains on the resources of a small tramway company, and it must be noted that these expenses have to be met in the preliminary stages of the project, when the money available is necessarily a speculative advance, which subsequently has to be paid for by the public at an enormous premium if the Bill goes through. Men will not provide the funds for bringing forward a project which after all may be rejected, except under the promise of such large gains that the possible profit to them justifies the risk of total loss of the sum advanced. These large sums afterwards, when the Bill goes through and the public subscribes the capital, form a first charge, and not infrequently impose a burden which swallows up all, and more than all, the profits from running the concern. By reducing these preliminary expenses to a nominal sum, all this, as will be seen, might be avoided.

Plans and Sections.—Here, again, great and unnecessary expenditure is involved in the adherence to old rules and regulations, which ought long ago to have been deemed obsolete, as the reasons on which they are founded admittedly are. In past times, when no ordnance maps were available, the usually inferior, although specially made, lithographic plans were necessary, but to-day they would be economically and advantageously replaced by ordnance maps with the line of the proposed tramway drawn upon them. Sections are not necessary, although according to rules they are required, for it is useless to give a section when nine words in the Bill inform the public that "the tramway level is that of the roadways traversed," and even in the case of railways where new levels are followed it should be sufficient to make it incumbent upon the promoters to supply at a nominal charge tracings of so much of the section as actually concerns any applicant.

Deposit.—In connection with light railways and tramroads or tramways, the deposit now required and the payment of one-half per cent. of the intended capital on the passing of the Act should either be materially reduced or abolished altogether. If these lines are to be made for the benefit of industries and populations now suffering from the want of sufficient means of transit, it is desirable that relief in this respect should be complete. Most of the lines would be constructed along or beside

roads, little land required, and (unlike a main line of railway which would render much property idle if not proceeded with after the Act) no losses would be incurred by any owners. There would, however, be no objection to a deposit after obtaining the Act and before commencing construction.

Committees.—The present system of legislation, which requires the promoters of private Bills to appear before separate committees of each House to prove the preamble of their Bill, is most prejudicial, and can be of no use except to the pockets of those whose duty it is to steer these Bills through the House. It entails a lamentable waste of time and of money that should be available for construction, and necessitates the duplication of the same identical evidence before each committee. An easy way of avoiding this difficulty, if the procedure is necessary at all, would be to appoint joint committees to hear the evidence of the opposition to all Bills. This would not involve any necessity for a joint decision, as those representing each House might be free to give their own independent decision.

Private Agreements.—In many cases it is necessary in private Bill legislation, especially where municipal interests may be involved, to require the promoter of any particular scheme to obtain consent from the local authority or local authorities within whose jurisdiction the proposed works would be before he can be heard on the merits of the Bill. The objection to this is that it unnecessarily and sometimes enormously increases the cost of passing Standing Orders. The law as it stands gives a fictitious importance to this consent, or an importance at an improper and harmful stage in the history of any Bill. In view of public advantage it is, moreover, a disastrous requirement, as it sometimes stops a useful scheme almost at the outset. Local authorities and other opposing interests are enabled to impose conditions almost prohibitory, but these conditions, as well as blackmail, are made the subject of agreements which the committees never see. Moreover, these conditions may be to the pecuniary advantage of but one or two of the members of a local authority, but if the promoter refuses to accept them, the influence of the one or two members may be quite strong enough to obtain the adverse vote of that local authority. That these things are done is only more discreditable to the local authorities than it is to the legislation that makes it possible. By assenting to these conditions or by payment of blackmail promoters have obtained Acts by proving to the committee that the Acts would be to the public advantage. But these Acts would probably not have been obtained if the

committee had known of the existence of these agreements, for they have in some cases doomed the projects to commercial failure from the first. If a project is likely to be to the public advantage, there should be no influencing conditions which may not be made public. The authors, therefore, hold that all agreements having any relation to promotion, construction or working should be supplied to the committee, and the committee should decide whether or not such agreements should be in the Bill, or modified, or struck out, whichever they deem best.

Estimates.—During the progress of both opposed and unopposed Bills, it is desirable that Parliament should consider closely the relationship between the proposed capitalisation of the company and the reasonable cost of the proposed work.

It is usual to restrict the amount of debenture in tramways to a quarter of the paid-up capital; but this is very little, if any, protection to the investor, as it is only necessary to make the share capital large enough to obtain debenture capital far beyond the value of the property. The necessity for the consideration of this matter by the committee is shown by an examination of the capital cost of tramways in the United Kingdom, without considering the debentures.

The tramway returns show that for every mile of tramway constructed in this country 15,000*l.* has been spent, which is about three times as much as a single mile of any ordinary tramway should cost to construct—that is to say, expenses other than those of construction and engineering, upon which a dividend could be earned, have gone in ways which have purchased no tangible asset. This money, nevertheless, has to be reckoned when the price of fares and rates have to be arranged. At the present moment no less than 1,750,000*l.* spent on tramways in Great Britain pays no dividend at all, and without doubt the chief cause of this is the disproportion between capital and true cost. The Acts for these tramways were obtained because "the construction of the same would be to the public advantage." The best advantage to the public in this case would be cheap fares, but such a very high capitalisation made it impossible to realise this from the first. The committee should therefore consider the relation between capital and reasonable cost, especially in connection with unopposed Bills.

Opposition.—It has been a common thing in the past for a promoter to be placed in such a position that he must either accept the clauses demanded by a wealthy and powerful opposition, and so do away entirely with the value of his Bill, or

abandon it. Even should he decide to fight it, his opponents have the power to extend the period of opposition for such a long time in both Houses that they can impose a burden in capital expenditure on the undertaking, which is so heavy that it cannot be borne without being seriously prejudicial to the advantages obtained from the Act. Opposition of this kind, even when the committee decide that the Bill would afford things "to the public advantage," cripples the undertaking and only gives the public something to which they may subscribe and upon which they may lose their money. The prayer is granted, but the grant is worse than useless as far as any public advantage is concerned. It is therefore very important that if the present system is continued, the powers of the committee, to make the losing opposition pay the whole cost of the inquiry, should be much more strongly enforced, especially if there should be any proof during the inquiry that the opposition is frivolous or due to mainly personal interest.

The enormous cost of obtaining the powers to construct the Manchester Ship Canal is a good example in connection with this argument. This Bill would never have become an Act had not the promoters been able to show the committee that the then existing monopoly, enjoyed by the railway companies, enabled them to charge a rate which was detrimental to the trade of Manchester and district, especially as this scheme was almost without precedent. The opposition, as subsequent events have proved, was clearly for the purpose of maintaining a harmful monopoly, and this Bill would never have been promoted except as a consequence of the existence of this combination, or, being promoted, would have cost a comparatively small sum to comply with Standing Orders. The committee, in giving their decision, might therefore very properly have ordered the various railway companies to pay the cost of the inquiry.

Delay.—The length of time at present absorbed in obtaining powers by means of private Bills or provisional orders might not perhaps be advantageously shortened to any considerable extent for the public works for which they are mostly required. There is, however, something very unreasonable in the system which makes it necessary to occupy half a year to get Parliamentary permission to carry out a project to which all the local authorities concerned have given consent. It is also absurd that the same length of time and the same machinery should be necessary to get permission to make a 10,000*l.* tramway as to make a 100,000*l.* railway.

Board of Trade Powers.—For the foregoing reasons it is

GILBERT WOOD & CO., 175 Strand, London, W.C.

clearly necessary that powers should be obtainable for the minor projects by some shorter and more rapid means of legislation. The authors therefore suggest that the Board of Trade should be given the power to hold local inquiries and grant permission to carry out schemes, just as the Local Government now conduct inquiries, and without the delay necessarily entailed for a confirmation Act. This would very materially assist enterprise on tramroads and other works, and would make it possible for a small tramroad company to proceed as cheaply as a private owner can with a line on his own property.

It is, moreover, desirable that private Bill procedure should be so amended that not only shall less of the time of those who may be called on to give evidence be wasted, but it should not be necessary to bring witnesses to London from Ireland and Scotland for the purpose.

As an example of the necessity for more freedom in the exercise of discretion with regard to mechanical and minor matters affecting tramroads, it may be mentioned that whilst every Tramway Act permitting the use of mechanical traction requires all steam locomotives to be fitted with automatic speed governors and brakes, a requirement which the Board of Trade officers are bound therefore to enforce, no such requirement is demanded by them with regard to electrical tramcars. They do not feel bound to enforce it because electric locomotives are not steam locomotives. Part of the South Staffordshire tramways is worked by seventeen electric motor cars weighing six tons each, where formerly it was worked by steam locomotives. On this piece of line no such automatic governors and connected brakes have ever been found necessary, neither have they at Leeds or Blackpool.

Clauses such as these inserted in Tramway Acts hamper the engineer in the proper working of a line, and the Board of Trade official becomes a mere clerk of works following a specification, whereas he should be free to insist on or to relax provisions with regard to mechanical details according to circumstances and to the requirements of the case as affected by progress in construction and by the demands of a district or by the kind of traffic.

The case of the Longton extension of the North Staffordshire Tramways is another of many examples showing the necessity for change with regard to the Board of Trade and the clauses in various Acts. The provisional order for this line was obtained after inspection and report by a Board of Trade inspector, but after the line was completed at a cost of about 25,000% the Board of Trade refused to pass it, because one

street through which it passed was below statute width, and with the result that although the Longton Town Council has done its best to get the Board of Trade to relax its requirements, yet that 25,000% of capital has been completely lost, and the inhabitants of Longton complain to this day of the want of tramway facilities.

It may not be necessary, but it will perhaps be as well to state that the authors have no intention of suggesting that the private interests of the promoter or promoters should ever be allowed to weight in the least as against the similar interests of individuals. They think, however, it is clear that, inasmuch as no public work of the kind here referred to should be permitted unless of public advantage, facilities should be granted for the promoters to show public advantage and merit before the opposition of the individual steps in.

It must further be pointed out that inasmuch as the promoter of a tramroad could not proceed without the consent of the majority of the inhabitants, it would be to the public advantage that the merits of a scheme should be considered before opposition to it is taken. In this way much of the vexatious opposition which at present adds greatly to the cost of a project would be avoided, and some of the agreements extracted from promoters before Standing Orders, and kept secret afterwards, would never have to be entered into. The private interests of individuals must be carefully guarded as now, but it is most desirable that when a scheme is declared to be a necessity and of public interest, that the merits of that scheme should be first examined, and if endorsed, then the objections should be heard with the object of modification so that objections may be protected and satisfied. If the wish of the public as shown by its consent is that a scheme should be carried, its rejection should not as now be based on the objections of a few individuals unless it can be shown that injustice would otherwise result. The authors are not suggesting any new form of legislation, this procedure being the universal order of procedure in France, and one which is also largely adopted in Belgium in connection with its numerous secondary railways and tramroads.

The result of this policy abroad is, for instance, in Belgium with a population of about six millions, that in addition to their extensive system of railways (which is greater in mileage per head of population than that of Great Britain), they have at the present moment 730 miles of light railways working, 40 miles in construction and 900 miles projected to be constructed, representing a capital of 4,888,000% or nearly 1% per head. It

may be suggested, therefore, that under reasonable legislation there is, on the same estimate, employment for about 35,000,000*l.* of capital in Great Britain on light railway and tramroad works. In 1893 the mean dividend paid on all the Belgian lines was equal to 2·8 per cent.

A SUB-CONTRACTOR'S ACTION.

THE case *Ryder v. Walton* came before Mr. Justice Charles at the Durham assizes. The plaintiff, Albert Ryder, claimed that on and subsequent to March 1894, he, at the request of and for the defendant Thomas Walton, did work in and about the dressing of stonework for Stanley Church, near Crook, and the defendant became liable to pay the plaintiff a reasonable price for the work so executed and for materials supplied, and a reasonable sum for the said work and materials now payable by the defendant to the plaintiff amounted to 342*l.* 10*s.* 7*d.*, which included 11*l.* 3*s.* 5*d.* extras, less 204*l.* 10*s.* paid by the defendant to plaintiff on account, leaving 138*l.* 0*s.* 7*d.* Plaintiff alleged that it was agreed that the whole of the new work had to be done at the plaintiff's yard, and the defendant to do all the cartage, but later it was agreed that in consideration of the plaintiff waiving his right to have the new work done in his yard, the defendant agreed to keep the plaintiff supplied with enough stone for fifteen men, and enable the plaintiff to get the work done quickly. The plaintiff commenced the work in accordance with the contract, and was ready and willing to carry out and complete the work, but the defendant did not keep him supplied with stone as quickly as required, and wrongfully took the work out of the plaintiff's hands and employed other men to do the same, and wrongfully repudiated his contract with the plaintiff, and exonerated and discharged the plaintiff from a further performance of the same, whereby the plaintiff lost the benefit of the contract. The plaintiff, in short, claimed 138*l.* 0*s.* 7*d.*

The defendant's defence and counter-claim was that plaintiff did not fully carry out his contract, but on or about July 5 abandoned the work, and withdrew his workmen and tools from the place. The defendant denied that he agreed to keep the plaintiff supplied with enough stone for fifteen men, and enable the plaintiff to get the work done quickly. The defendant did, in fact, supply the plaintiff and kept his men fully employed. He denied that he ever took the work out of the hands of the

plaintiff or repudiated his contract with the plaintiff. Defendant had, in fact, paid the plaintiff 204*l.* 10*s.* on account of the materials supplied and work done. He contended that by reason of the plaintiff's breach of contract he had suffered damage, and had to employ other workmen at a cost of 150*l.* 0*s.* 11½*d.* to complete the work contracted to be done by the plaintiff. Defendant had also had to pay extra carriage on stone to the amount of 24*l.* 14*s.* 6*d.*, obtained at plaintiff's request, from Denwick, near Alnwick, which extra carriage plaintiff agreed to pay. The said two sums, with the 204*l.* 10*s.* paid to the plaintiff, made a total of 379*l.* 5*s.* 5½*d.* actually paid by the defendant in respect of the contract, and the defendant claimed to recover from the plaintiff 88*l.* 18*s.* 3½*d.*, being the difference between that sum and the sum of 290*l.* 7*s.* 2*d.*, made up of the 288*l.* contract price and 2*l.* 7*s.* due to the plaintiff in respect of extras admitted.

Mr. Manisty, in opening the case, said there were two questions for his lordship to decide. First of all the question of whether or not the contract was broken by the plaintiff or by the defendant; if it were broken by the defendant they claimed on a point of merit. There was a special contract in the case, and if it were repudiated or broken by the defendant so as to entitle them to treat the contract as reasonable, then they were entitled to payment on point of merit.

Mr. Waddy said the case was purely a question of fact; there was no law in it.

Mr. Manisty thereupon proceeded to narrate the facts of the case, and said that the defendant had contracted to do the whole of the works in connection with the repair of Stanley Church. He sub-contracted with the plaintiff to 'do the stone work, and agreed that the interior was to be of Denwick stone, and the exterior of Witton-le-Wear stone. Plaintiff's tender was put in the form of the following:—"I hereby offer and agree to execute the whole of the labour in dressing of the whole stone-work for the above in accordance with plans and specifications to the entire satisfaction of the architects for the sum of 288*l.*" Stanley Church was two miles from Crook, at a considerable elevation above Crook, and though it was in that agreement also stipulated that the plaintiff should do the stone-dressing at his own place in Crook, it was afterwards agreed that the plaintiff should have his men on the spot at the church and there dress the stone. That being so it was important that the plaintiff should get the work over as rapidly as possible, as he would have to be away from his own shop, and the defendant undertook that he would keep plaintiff supplied with sufficient

stone to keep fifteen men going continually to complete the work in six weeks. But it turned out that at no time was there sufficient stone for the plaintiff to keep fifteen men going, and he never had more than thirteen at any time.

Albert Ryder, the plaintiff, stated he carried on business at Crook, about two miles from Stanley Church. To the latter place it was all uphill from his place, and on an elevation of something like 600 feet higher. Speaking of his offer to the defendant, he said they agreed that he should do the interior of Denwick stone and the exterior of Witton-le-Wear stone. They subsequently arranged that the contract should be varied, and that the work was to be chiselled in the premises of the church. Defendant spoke of getting the nave finished in six weeks, and they having calculated that to do that they must have fifteen men going, defendant agreed to keep fifteen men supplied with stone to work. They never had sufficient stone to keep fifteen men supplied. He constantly grumbled about the short supply of stone. On June 20 and between that day and July 5 a rolley load of stone was sent daily, which was not half enough. In answer to his lordship, witness said he never did have fifteen men. He had never more than thirteen, and the average was nine; the reason he had no more engaged was because he could not get stone enough. A rolley load of stone was not enough to keep six men going. He complained to Walton between the dates named, and on July 3 he had a discussion with the defendant as to the payment of 5*l.* 2*s.* extras ordered by building committee. On Thursday morning, July 5, at nine o'clock, he was going along the road, and passed a load of stone going in. When he got up to the church he found the men doing practically nothing, and including the rolley load which he had passed, the men had finished the whole of the stone on the place by one o'clock, showing that there was a very insufficient supply. There was that day no raw stone for the men to go on with; and the men demanded their money. Plaintiff then went down and saw the defendant at his yard in Crook, and told him that the job was stopped for stone and the men were asking for their money. Defendant and he tried to persuade the men to go back, and defendant took them into a public-house and stood two rounds and plaintiff stood one. Defendant then went away. Plaintiff at no time intimated to the defendant that he was throwing up the job. Plaintiff did not pay all the men off that night, but he paid all off but two and a boy, those whom he paid being the men who refused to go on any longer. Next morning plaintiff went up to work with his son, and took a cart for the tools of the men who had

stopped work the previous day and refused to go on again. When he got there he was joined by his apprentice. They were all in their working clothes. When he got up he found three men in the shed, who had started work. They were three of the men he had had working for him the day before. Plaintiff put his tools into the cart. He placed the matter in the hands of a firm of solicitors.

Before plaintiff was cross-examined it was announced that the litigants had consented to the withdrawal of the case, no conditions being stipulated in open court.

PATENTS.

[This List of Patents is compiled specially for this Journal by Mr. G. H. Rayner, of the firm of Rayner & Co., Consulting Patent Agents, 37 Chancery Lane, London, W.C., from whom all particulars and information relating to Patents may be had gratuitously.]

Architect and Contract Reporter.

NEW READING CASE.

To Librarians of the Public Libraries and Reading-rooms.—A new handsome Reading Case can be supplied at a nominal charge of 2s., by post 2s. 6d., on early application to the Publisher, 175 Strand, W.C.

SPECIAL NOTICE TO THE TRADE AND OTHERS.

[Extract from a lecture on Architects' Libraries by Professor T. Roger Smith, F.R.I.B.A., at University College, October 10, 1893.]

"Lastly, let me recommend the back volumes of the professional journals. In the course of years all sorts of architectural topics come up in the public press and before the professional societies, and if you hunt through the indexes of these publications when you are seeking for information which eludes you in books, you will often be rewarded."

There has been a considerable demand for the back numbers of *The Architect* during the last three or four months, which we have no doubt has arisen from the remarks made by Professor Roger Smith, as contained in the above quotation; but the consequence has been that our stock of back numbers is getting very low, and consequently, in future, the charge for back numbers of previous date to January 12, 1894, will be 6d. each.

A few of the back volumes may still be had, price 12s. each.

EDITORIAL NOTICES.

The authors of signed articles and papers read in public must necessarily be held responsible for their contents.

No communication can be inserted unless authenticated by the name and address of the writer—not in every case for publication, but as a guarantee of good faith.

Correspondents are requested as much as possible to make their communications brief. The space we can devote to Correspondence will not usually permit our inserting lengthy communications.

TENDERS, ETC.

* * As great disappointment is frequently expressed at the non-appearance of Contracts Open, Tenders, &c., it is particularly requested that information of this description be forwarded to the office, 175 Strand, London, W.C., not later than 5 P.M. on Thursdays.

WINSOR & NEWTON'S

"Waterproof"

INDIAN INK.

This new preparation—made from genuine Indian Ink—has been introduced to meet the requirements of those Artists, Architects and Designers who wish to lay washes of colour over drawings in ink.

Unlike many so-called Indelible Inks, "Waterproof Indian Ink," when dry, will be found absolutely unaffected by subsequent wetting.

SPRING NOVELTIES.

WITH the return of spring comes the display in our shop-windows of those products of the factories, both English and foreign, which have for many months been engaging the close attention and thought of artist, manufacturer and workman, and it is with no little interest that we pass from window to window in our chief thoroughfares to note the direction in which these efforts have been directed. We are glad to see that the English designer more than holds his own, and that, while the foreigner is satisfied to repeat and repeat what he has done for many a year, our own manufacturer is bringing to the front that freshness which makes us feel that we are not merely living, but growing. Among these new productions wall-papers keep very much to the front, and it is to such houses as Jeffrey & Co., the well-known paper-stainers, of 64 Essex Road, Islington, that we look to show us the latest phase of thought in this direction, and withal to give us that which will beautify our homes at a small cost. We lately had the opportunity of visiting their factory, and were much interested in finding that they had added a very spacious showroom, where they had a grand display of such wall-papers as we have been referring to, and when we say that the designers of these include such well-known names as W. Crane, Lewis F. Day, Heywood Sumner and Stephen Webb, all members of the Arts and Crafts Exhibition Society, it is but saying that their showroom becomes an exhibition in itself and that it is well worth a visit. We noticed that many of the wall-papers from these artists were quite simple in character and thus come within the range of all buyers, and this remark more especially refers to W. Crane's "Teasle" and "Lily Rose," Heywood Sumner's "Fig and Olive" staircase

"MANCHESTER," DYNAMO.

paper, and also to S. Heywood's "Giant Hemlock" and S. Manson's "Ispahan." The friezes by Stephen Webb which are embossed in high relief should be particularly noticed, for not only are they embossed in leather paper, but Messrs. Jeffrey & Co. have also produced them in embossed copper, and in this form they make beautiful panels above a high wood dado or for introducing as panels in a frieze. The show-room is also rich in the finest wall-papers which are produced; embossed leather papers, lacquered golds and flocks, including the latest novelty in this direction, viz. the "real silk" flocks, which have all the value of silk hangings. But we notice that one part of the room is entirely devoted to their machine-printed papers, which, if we mistake not, were being printed immediately under the floor on which we stood. Such papers, although made in such large quantities that they become quite inexpensive, are of such high order that they lose nothing in effect by being exhibited in close proximity to those which are printed by the more laborious and therefore more permanent process of block printing.

THE BUILDING EXHIBITION.

THE Building Exhibition duly opened on Monday morning, this week. It is satisfactory to be able to state that the evidence of success was visible from the first day. The exhibits are not only attractive, but have sustained the examination of experts. As far as we have been able to ascertain, the visitors to the Agricultural Hall have expressed satisfaction with the show, and we have no doubt that many orders were booked by the exhibitors, and they deserve encouragement for producing so much excellent work. In our issue of *The Architect* of the 22nd we gave particulars of several notable exhibits, and among them those of Ellis, Partridge & Co., Stanley Bros., S. & E. Collier, H. J. & C. Major, John Grundy, Gibbs Bros., L. V. Riley & Co., the Incandescent Gas Light Co., Limited, the Kauri Timber Co., Charles Erith & Co., Robert Adams, John Tann, Arthur W. Adams, the Vitreous Enamelled Glass and Tile Co., Herman & Co., &c.

Somerset Trading Co., Limited.

The Somerset Trading Co., Limited, of Bridgwater, at Stand No. 164, Row F, have a small shed erected and roofed with their improved plain tiles (a specialty with this firm), with barges, hips and valleys. These tiles are manufactured by a patented process under heavy pressure, making them non-porous; they are free from kiln-cracks, tough and of a pleasing colour. Size, $10\frac{1}{2}$ inches by $6\frac{1}{2}$ inches, and if laid to 4-inch gauge 550 cover a square. They also show other roofing tiles of their manufacture, namely, an improved triple angular tile having several advantages over the old pattern; they can be used with battens to different gauges in straight courses or with break-joints; an interlocking double Roman-square shouldered to break-joint; their patent Holdfast double Romans, which cannot be blown off a roof, all being locked together; the ordinary double Roman and triple tiles; Poolet's patent bonding roll, and Phillips's patent Lockjaw tiles; superior machine-made ridge tiles, beaded and ornamental, of various patterns; also, made by a patented process, a variety of finials, moulded, front and string-course bricks with returns, &c.

Frederick Jones & Co.

Messrs. Frederick Jones & Co., of Perren Street, Kentish Town, as usual, have a thoroughly practical exhibit of their well-known silicate cotton specialties for fire-proofing and sound-proofing purposes, for which they have obtained numerous medals and diplomas during the past twenty years. This firm also has an effective display of fibrous plaster slabs, as well as ornamental ceilings, cornices, &c., a branch of their business in which they are now obviously able to compete with the leading houses in the trade. The various fire and sound proofing methods introduced by Messrs. Jones & Co. are well illustrated at their stand by models. The power of silicate cotton to stop the transmission of sound is demonstrated by a wooden box lined with silicate cotton in which an alarm clock is placed—no sound whatever being heard the moment the lid is shut. This firm's patent "combination slabs," i.e. plaster slabs padded on one side with silicate cotton, are especially deserving of attention as a most effectual mode of rendering floors, walls and partitions totally fire and sound proof by one process, and obviating the use of the old-fashioned

CARVED OAK AND ANTIQUE DEPARTMENT, No. 204 TOTTENHAM COURT ROAD.

sound-boarding and lath and plaster. The same patent system is also applied to casings, ornamental or plain, for iron columns, girders, &c. When the disastrous effects of the recent frost are painfully fresh in the minds of householders, it may be remarked that silicate cotton applied to pipes and cisterns is a preventive against the effects of frost. Messrs. Jones & Co. have some excellent methods of protecting pipes and cisterns. Their "strips" are so made as to wind spirally round pipes of any diameter, and they will not fail to commend themselves for their cheapness and simplicity.

W. Gooding.

The patent interchangeable rubber stair-treads shown are admirably adapted for railway stations, railway and other carriages, tramcars, omnibuses, footbridges, public buildings, hotels, warehouses, factories, hospitals, schools, theatres, music halls, Turkish and public baths, ships, yachts, aisles of churches, pulpit stairs, office stairs, landings, restaurants, public houses, entrances to shops, private houses, &c. In every case stair-cases for public use get unequal wear, but these patent rubber treads hold their own for years against wear and tear. The rubber treads, speaking from memory, are nearly 2 inches square, and can easily be replaced if worn. According to circumstances the wear and tear may be either central or at the sides. This system gives a safe foothold and is very slight in appearance. It is also inexpensive, the cost of replacing worn rubbers being small and no labour involved.

Ashmore, Benson, Pease & Co., Limited.

This exhibit is of great interest to architects and builders. The principal feature of the exhibit, as we saw it, was the demonstration of the uses of a tubular system for building purposes, for tubular walling, tubular flooring, tubular columns, &c. Pease's patent system of interlocked tubing of thin metal sheeting, it is named. The advantages claimed for the system are too numerous to mention, but among them it may be stated that for walling it is compact, strong and fireproof, without rivets or visible joints, and presents a smooth metal surface. It can be plastered or tiled, is self-supporting over a large span, and useful for ventilating purposes. It may be filled with various materials, and is a strong wall when not filled. For flooring and as columns similar merits are claimed in the way of strength, fire-resisting qualities, &c. This exhibit should be inspected.

Simplex Window Company, Limited.

This firm have received many valuable testimonials in regard to the value of their "Simplex" window-sash fittings, which no doubt may be claimed as the cheapest and simplest means of raising, lowering and fastening a window-sash in the market. One great advantage is that the sash can be cleaned without risk to life.

Marpedo Compound Company.

What is styled "Marpedo" is exhibited by the above company, and should be inspected. It is shown as "the perfect sanitary washable paint," varnishable without size. Of course it is a substitute for oil-paints and processes of distemper, and has great covering powers, as may be expected in all substitutes for oil-paints. Sundry details as described to us have enabled us to recommend "Marpedo" for practical use. Space will not allow of giving any explanations at length. The "Marpedo" is a washable paint. Samples of it are shown, but nearly every shade of tint and colour may be obtained.

Shanks & Co.

Messrs. Shanks & Co., of Barrhead, Glasgow, and 46 Cannon Street, London, E.C., have as usual a high-class exhibit—an exhibit, it may be said, surpassing the usual degree of interest. In sanitary appliances the firm never rest in devising improvements, and the good work shown one year is bettered in the next year. Baths, lavatories, closets, &c., are shown. In baths, a solid porcelain bath, a *fin-de-siècle* parallel, extra large, and large taper, also a modern taper, modern, and new cheap independent spray. In lavatories, new modern, Imperial and other lavatories, plain and decorated; a new tubal lavatory, with modern waste; range (school), fireclay; range, "Instantan," fireclay; range, "Unus," solid fireclay with marble divisions, automatic tank, &c., complete; folding enclosed urinal, self-acting. In closets, the new Barrhead syphonic, 2 gallons, and same 3 gallons; the new Severn, 3 gallons, shown in action; Imperial combined with syphon cistern, in action. The appliances now shown are characterised by efficiency with great economy as to cost. One or two new closets are shown with lifting mahogany seats, which are quite good enough in appearance, while the price is within the means of a cottager. The closet is a new syphon closet, the one having a flush of 2 gallons and the other of 3 gallons. There is a large water surface. There is a water-seal of 8½ inches, and the closet has a single trap. This latter closet Messrs.

F. W. DECKER & CO.,

23 GARLICK HILL, CANNON STREET, LONDON, E.C.

(NEAR MANSION HOUSE STATION)

Shanks & Co. may be justly proud of, for we doubt that at the price a better flushing closet can be found in the market.

Yates, Haywood & Co.

A large space has been taken in the Hall by this firm for the display of their beautiful marble and wood chimneypieces, iron mantel registers, tiled register stoves, fenders, tiled hearths, &c. A feature of the exhibit is their patent "Quadrant" kitchener, which is to be seen in action. It has a lifting fire arrangement of an excellent kind, without rack or catch to get out of order. In addition, it can be used as an open or closed fire; it will burn anthracite coal, and also in the consumption of fuel is very economical.

The Granitic Paint Company.

The samples shown at this stand are well worth attention. The company obtained a silver medal at the Health Exhibition, 1884. The granitic paint has been under trial for thirty-four years and has stood the test successfully. It is adapted for painting of every description, either internal or external; for the finest decorative purposes, or as a preservative for coarse and rough materials. It possesses great fineness, covering properties and durability, has a highly-finished appearance and dries very hard, on which account it is specially suitable to all horticultural purposes. It does not blister, neither heat, moisture, sea air, nor frost, having any effect on it, and is, therefore, particularly suited for tropical or cold countries. It will preserve wood, iron, &c., from rust and decay, and will make joints in ironwork equal to red lead. Some specimens of decorative painting on canvas are shown. These were painted in 1883, and when lately removed the canvas was found quite discoloured by damp, though the painted face is as good as when first done.

The Self-Lock Roofing Tile Company.

A model building, occupying a space of about 16 feet by 17 feet, covered in self-lock roofing tiles in three sizes, viz. 6-inch, 9-inch and 12-inch. These tiles are suitable for mansions, churches, board schools, dwelling-houses, factories, warehouses, farm-houses and public buildings. They are constructed with a special machine, with cement and sand in certain proportions, unskilled labour only being required in their manufacture. The machine can be seen at work in the exhibition. It will be seen that these tiles embrace every advantage of strength, durability, lightness, application, treatment, and cheapness, the cost being about one-third of any

other roofing material now in use, in addition to which the woodwork required in constructing the roof would be 50 per cent. less than that required for the Broseley or other tiles. A guarantee would be given that a roof constructed in accordance with the instructions given by the Self-Lock Roofing Tile Company would be rain and storm proof. They can be used in any climate, and have for years been universally used in America, Canada, and Europe. The tiles can be used for a roof of ordinary pitch, or as low a pitch as one-seventh, and they can also be hung perpendicularly for walls. The usual colours kept in stock are red, blue, or cement colour, but they can be manufactured in any other colours which may be required. It is the intention of the company to sell the machines and grant licenses for the manufacture of the tiles in various parts. We have referred before to these tiles and can only say in conclusion that now that we have seen them fixed we feel convinced that our previous remarks with reference to them were fully justified. The exhibit at the Hall is one of the best in the exhibition. Full particulars of these arrangements can be obtained at the exhibition, or at the offices of the company, 47 Victoria Street, Westminster.

C. D. Phillips.

We refer to Phillips's patent Lockjaw tiles in another paragraph, as manufactured and exhibited by the Somerset Trading Co.

The Anthydor Compound General Paint Company, Limited.

The "Anthydor" is a sanitary paint, being a substitute for oil paint and distemper. It is non-poisonous, odourless, damp-proof and durable, and will not crack or blister through heat or rub off or decompose. The paint has been used in painting all the woodwork of the model building erected by the Self-lock Roofing Tile Company. It can be used either for inside or outside work, and is applicable on either brick or plaster walls, wood or ironwork, and it can be varnished if required without size, when a surface equal to the best enamel is obtained. The compound simply needs the addition of tepid water and is ready for use, when it is cheaper than oil paint by 60 per cent, as 1 cwt. will cover 1,200 super yards. It can be had in any colour and all the newest art shades, and will not fade. It is unsurpassed for either interior or exterior decorations, for either plain colouring or artistic treatment, the colours being intermixable and drying with a perfectly flat and uniform surface. It dries very rapidly, and several coats can be applied in the space

of a few hours, and in fact a room can be inhabited an hour afterwards.

The Eagle Range and Foundry Company.

An interesting variety of cooking ranges are shown, and some in operation, at the stand of this company. A special new range will attract the attention of many. It is exhibited in two kinds. A valuable feature is the application of a safety-valve with double action, fusible plug and spring, which, if anything can do so, will secure immunity from the boiler explosions which have been too frequent this winter. The dampers are worked by an extremely ingenious method by rod and handle. The handle shows on an enamel plate whether the damper is set to "fast," "medium," "slow" or "closed," and each oven has its separate damper rod. The ovens are furnished with a glass door in addition to the usual metal door, and the process of the cooking can be inspected without altering the temperature of the oven. A regulator outside shows the exact temperature of the oven. This registering instrument only costs a few shillings, being independent of quick-silver for its action.

W. A. Smith.

Mr. W. A. Smith, of the Midland Machinery Works, Northampton, exhibits an improved horizontal brick, pipe and tile making machine, price 21*l*. What is called a No. 4 machine is provided with many important improvements, and will make solid, perforated or tubular bricks and pipes, either round, egg-shaped or octagonal, from 1 inch to 12 inches diameter when burnt; plain, corrugated, Roman, pan, garden and ridge tiles of various patterns. The cutting-off table is arranged for either bricks, pipes or tiles, and can be easily adjusted to cut off various lengths; double racks and pinions are fitted to this machine, and a second wheel is also supplied free of charge to alter the speed, so that the machine can be worked by either a man or a lad, as may be more convenient. It will produce 6,500 pipes 2 inches internal diameter per day of ten hours, and other descriptions of goods in proportion. The power is applied in the most convenient part of the machine for economical and effective working. Mr. Smith is also maker of Nos. 1, 2 and 3 sizes-similar type machines, at prices ranging from 12*l*. He also exhibits a very compact set of improved clay-crushing rollers for steam or water power, which may be used for crushing marl, stony or rough coarse clays, where it is necessary to reduce them to a fine state previous to their being made into bricks, pipes or tiles either by hand or by machine.

ILLUSTRATIONS.

CORRIDOR, GOSFORD HOUSE, LONGNIDDRY, N.B.

NORTH-EASTERN STATION HOTEL, ENTRANCE HALL.

ENTRY OF ALEXANDER THE GREAT INTO BABYLON.

He also exhibits an improved cutting-off table, portable railway wrought-iron brick-truck on springs, large quantity of dies of all shapes and an assortment of accessories for brickyards and building trades, such as machinery oils, wire, lifting, push and pull screw-jacks, waste, packing, &c. Also an iron table circular saw-bench, which will carry a saw up to 36 inches, the table being 5 feet by 2 feet 8 inches. This saw-bench is of a very massive and heavy description, and is fitted with fast and loose pulleys, striking gear, &c.

Messrs. Freeman Bros.

Messrs. Freeman Bros., 99 York Road, Battersea, patentees and sole manufacturers of the patent "grip-joint" connections for securely joining lead pipes to earthenware, exhibit their patent grip-joint connections, their patent adjustable pedestal water-closet "Turritt," patent junctions for connecting lead soil-pipes, washes, anti-syphon pipes, &c., to iron pipes; the "Triple Alliance," a combination of the three foregoing; "Desideratum" pedestal closets, specially made copper cylinders and boilers for domestic hot-water work, drain-cleansing and chimney-sweeping machines and appurtenances.

Opalite Glazed Brick Co.

The National Opalite Glazed Brick and Tile Syndicate, Limited, of 142 Charing Cross Road, London, W., and 26 Pall Mall, Manchester, are exhibiting some very beautiful specimens of glazed bricks and tiling on a totally new principle. By their letters patent they bring into the market a new material, known as "Opalite," which is manufactured from the finest opal, and by means of a compound cement which they specially make they unite the "Opalite Tablets" to any ordinary brick, and to brick and stud partition walls. The bricks can be handled and applied in the same manner as is usually done with the ordinary glazed bricks. "Opalite" has but to become more generally known to insure its due appreciation from those concerned in the building and equipment of

hotels, clubs, cafés, hydropathic establishments, restaurants and other public buildings. It will also be found most suitable for the embellishment of the interiors of confectioners' shops, dairies, bakehouses, corridors, bathrooms, lavatories, kitchens, larders and other domestic offices; in fact, wherever permanent decoration, combined with beauty in design, durability and cleanliness, are concerned. Among the many special advantages claimed for this new material is its great superiority over the ordinary tile and glazed brick of the present day, for whereas work constructed of these last-mentioned materials fails in its decorative appearance no less than in its durability when used for sanitary purposes, "Opalite," on the other hand, as applied by the Syndicate's process, is ever fresh and new in its appearance, charming in colours and most durable. When we add to this the fact that it can be faced to new or old walls alike by any ordinary bricklayer or plasterer with the same success, while its price is less than ordinary tiling, we feel assured that "Opalite," when brought fully before the public, will be generally adopted, and thereby revolutionise this branch of the decorative building trade. "Opalite" should be found invaluable as a reflecting agent where borrowed light is a necessity, giving as it does a brilliantly polished surface, and surpassing in many respects the reflectors now in common use.

James Adams.

Mr. James Adams, Stand No. 139, Row E, inventor of the original pneumatic check and spring for the floor, exhibits his latest improvements, which are worthy of special attention. One is a neat back spring for doors, which can be readily charged against boisterous winds. This should interest licensed victuallers, who have doors in exposed positions. Another, silent-closing door springs, which he has named the "City," contains advantages which have long been required. Among his other exhibits are the single and double action pneumatic check springs well-known as the "Slave" patent, and the shallow well, adjustable, double-action spring hinge; also a very neat sash-fastener, which defies the burglar's knife, and will lock the window open for ventilation. Architects and users of door springs will not regret paying a visit to this stand.

Tangyes, Limited.

Show gas-engines at work on the "Otto" principle (Pinkney's patents); also an engine worked by oil; also a selection of lifting screw and hydraulic jacks, rope and chain

blocks, pumps and other builders' tackle. The petroleum (or "oil") engine is specially suitable for farm-servants, whose duty is not supposed to consist necessarily in experience of mechanical processes. No special oil is actually required. It is easily managed by any person, and no question of insurance has arisen during its use.

King & Son.

The exhibition would scarcely seem complete without one saw the patent honeycomb wine bin of Messrs. King & Son, of Stow Works, Weedon, on view. It consists of a honeycomb of terra-cotta tubes stacked against cellar walls, circular interiorly to fit the bottle, and several-sided exteriorly, which enables them to be stacked to any height with absolute firmness. These receptacles being of terra-cotta, syringing them with water in hot weather would keep the wines very cool.

R. W. Hitchins.

Shows Hitchins' new patent machine-made fibrous slabs, fire-proof slabs, sound-proof slabs, damp-proof slabs, pugging slabs, &c.; patent non-conducting compo for covering boilers, hot flues, steam chests, steam and water pipes, and all other heated surfaces, refrigerators, electric leads, &c.; patent stair coverings for renewing worn stairs, steps, &c., for prevention of slipping, deadening of sound, &c.

Turpin's Parquet Floor Joinery and Wood-carving Company, Limited.

This company still keeps to the front in their excellent works for wood parquetry, both in material and design, and they also have a happy knack in skilfully arranging harmonious combinations of different coloured woods.

Blackman Ventilating Company, Limited.

Two peculiarly interesting exhibits are shown for heating and ventilating purposes. The use of one is for general heating and ventilating of a house throughout; the other is for warming and ventilating separate rooms. Any convenient spot in the basement will serve for the apparatus designed for the whole house. As a combined system of warming and ventilation it is admirable, complete control over the temperature being afforded. Shortly we hope to forget the extremely cold weather, but it often happens in the summer months that the conditions are entirely reversed, and any appliance that will secure a pure atmosphere of cool air is desired, and arrangements are included where necessary for purifying the air before admission to the building. From inspection of the method by

A PERPLEXED GAS INSPECTOR.

"There has been so great a reduction in our consumption of gas at Speke Hall, Battersea, since we had your CLAPTON LIGHTS, that the Gas Company declared our meter must be out of order. They have had it examined, and can find nothing wrong."

R. H., London, September, 1893.

The Gas Light also at this Hall is said to be over twice what it was before.

J. C. HALLIDAY, INVENTOR AND MANUFACTURER,

12 GRAINGER STREET, NEWCASTLE-ON-TYNE.

A LIST of ART PLATES published in "THE ARCHITECT" will be forwarded on application to P. A. GILBERT WOOD, Publisher, 175 Strand.

which these machines play their part in warming and ventilation, and also from inspection of the working drawings, the system must be most satisfactory.

Charles Gay Roberts.

The very useful patent rain-water apparatus is shown at the stand of Mr. Charles Gay Roberts, of Haslemere, Surrey. The apparatus is well known for its extreme utility, especially in country parts, by its procuring a store of pure water, during showers and rains, from roofs of buildings, the ingenious part of the invention being a simple contrivance which sends to the waste all water until the roofs have been thoroughly cleansed of all dirt, soot, dust, &c.

Minton's, Limited.

Show a model structure displaying the excellent arrangements in wall-tiling, &c. Figured panels nicely designed are shown—dados, wall enrichments, &c. Inside the little structure is quite a museum of samples of tile-work, up to the best standard always maintained by this firm.

Joseph Arnold.

At his stand Mr. Arnold invites the attention of waterworks engineers, local boards, sanitary and urban authorities, corporations, &c., to his "Special Filter Sand," being, it is stated, pure silicate, even grain (coarse or fine), free from all impurities, requiring no washing or other preparation before using. It has been supplied to the principal water companies, sewage works, &c., in London and the provinces. Mr. Arnold says it is highly recommended by analysts and engineers for water and sewage filtration. This sand can be had in large or small quantities. Splendid samples are shown, and the system could not be too highly recommended.

Plastic Marble Company.

Among some of the advantages claimed for the patent plastic marble are the following:—That when finished it is part and parcel of the wall, and cannot warp, bulge, or in any way become detached from it; no screws, dowels, &c., required; that it has a hard impenetrable surface, and is specially useful for hospitals, &c., as it does not harbour disease germs; that it is from one-third to one-tenth the price of coloured marble, and when finished experts are unable to distinguish the difference; that there is no risk of breakage or damage in transit from works, as it is made and fixed up on the spot in its plastic state, therefore all risks are avoided; that for covering iron

columns it far surpasses anything else ever yet invented, and can be applied in houses already erected or in course of erection; also for covering walls, dados, skirtings, &c., and for pedestals, panels, chimney-pieces, table-tops, &c.

The Anti-Freezing Air-Valve Company.

A simple but most useful system is shown which has secured the unqualified approval of the New River, West Middlesex, and other water companies throughout the kingdom. This valve being screwed on to a base in the cistern, it is portable, and can be removed from one cistern to another. It is actuated by a bell wire, with catch attached. By pulling down the catch the wire acts upon a lever at the top of the valve; then by turning on the tap any quantity of water can be obtained. Directly the catch is released the valve falls into its seat, the water runs out of the pipes, being replaced by air, which comes through the T-piece as shown on the top of the valve casing, which is packed. By the application of this system the following, amongst many other advantages, will be obtained:—Frozen pipes become an impossibility, as the pipes will always be empty (if the taps are left open), and therefore they cannot burst; if by an almost impossible conjunction of circumstances water did remain in the pipes, they then froze and the pipes burst, still, as the valve in the cistern must be down in its seat, and no more water can come from the cistern, the only trouble would be about a pint of water contained in the pipes would come into the house, instead of the whole contents of the cistern; the valve being at about 2 inches from the bottom of the cistern a pure supply of water can always be obtained without disturbing the sediment at the bottom of the cistern; except in the very severest of all weathers, when the water in the cistern becomes a solid block of ice, there will always be a supply of water from the cistern; the use of this valve absolutely prevents waste by leakage; it is especially advantageous for use in stables and places where cattle are kept.

The Cheerful Fuel-Saver Company

Are exhibiting an entirely new form of economiser, which appears to possess all the necessary qualities for efficacy. By its use the heat, of which so large a proportion usually ascends the chimney, is thrown forward into the room, complete combustion is effected, and a bright cheerful fire produced. It obviates the use of fire-bricks and sides, which it effectually replaces, and the fuel is very largely economised.

SPRINKLER, Closed.

ALL
MILLS, WAREHOUSES, THEATRES AND PUBLIC BUILDINGS
CAN BE RENDERED ABSOLUTELY FIREPROOF BY ADOPTING

THE GRINNELL SPRINKLER

THE ONLY SPRINKLER WITH A RECORD.

Has Extinguished 2,000 Fires with an Average Loss of £50,
Protecting Property to the Value of £120,000,000.

Unlike all other Sprinklers, the GRINNELL is constructed entirely without Springs, Screws, Hinges, and other Mechanical make-shifts, so liable to derangement.

IT IS THE LEADING FIRE APPLIANCE OF THE DAY.

No. 2.—AUTOMATIC SELF-LOCKING ACTION.

No. 3.—THE SELF-HELP FASTENER.

A large number already in present use giving full satisfaction. Unrivalled. you require them for single or for double casements.

COMBINED STAYS AND FASTENERS FOR CASEMENTS AND FANLIGHTS.

WE beg to call your special attention to our Patent Combined Stay and Fastener, which, from its great advantages and easy mode of use, can well claim a superiority over the common kinds. You will notice that this Fastener has no complex system of working, is easy to fix, and, whether the casement is open or shut, does not project into the room, but hangs down the centre of the sash free from curtain or blind. The advantage of this Patent Fastener is that, being fixed in the centre of the sash, it affords protection against sudden gusts of wind when open, and keeps the sash safely closed when shut, as it acts as a fastener for the casement as well as a stay. Each of the three kinds of Fasteners affords the same advantages in all respects, as, though varying in shape, size, and price, are only different ideas of the same method. These Casement Fasteners can be used both for wood or iron, for single or double casements. The special pattern is used for fanlights to open outwards, and all can be used both for right or left hand. We can supply these Fasteners in any number of links, according to the extent the casement is required to be opened. We may also note that the Fasteners are well made and finished, can be had both in brass and iron, and are, therefore, well suited for any kind of residence. Quotations and further information will be given on application. Also testimonials. Please state in ordering whether

Stay and Fastener shown in Action.

Joseph Lewis.

In reference to the particulars furnished us of this exhibit, published in *The Architect* of March 22, Mr. Lewis writes to make the following correction. He says:—Lines 12 and 13, as far as "&c.," are foreign to the coupling which is being described; they should follow the word "purpose" on line 16 as a distinct and complete sentence.

The exhibitors are quite to be congratulated for their, no doubt, hard labour in contributing to a fine show.

Unavoidably, and in some cases by request, notices of several exhibitors are deferred till next week; but we would recommend that visits should be paid to the exhibits, and among these exhibits, which we trust to refer to next week, we may specially mention those of W. H. Harling (mathematical instruments); Joseph Williamson & Co., of Wellingborough (improved ranges, &c.); G. Shrewsbury (bath-heaters, gas-boilers and portable hot-water apparatus); John Line & Son (artistic wall-papers, &c.); Henry Bassant (parquet flooring); the Bristol Pennant Stone Firms, Limited (well known for their monumental work); T. Freeman, of Phoenix Street, N.W.; the Stourbridge Fire Brick Company; the N. A. P. window; the paragon bolt and various exhibits of machinery, &c.

TRADE NOTES.

THE Borough Hospital, Plymouth, is being warmed and ventilated by means of Shorlands' patent Manchester stoves, with descending smoke flues, the same being supplied by Messrs. E. H. Shorland & Brother, of Manchester.

THE monthly meeting of the London and Provincial Builders' Foremen's Association will be held to-morrow, the 30th inst., at 7.30 P.M. A paper will be read by Mr. Ackerman on "Present-day Apprenticeship."

MR. T. FREEMAN, of 200 and 202 Phoenix Street, N.W., informs us that he no longer does business with Messrs. P. & S. Wood, of West Bromwich, but supplies blue Staffordshire goods of his own make or selection from his stores at St. Pancras Station.

WE understand that Mr. Arthur Rutty has secured the contract from the London County Council to scarify the Victoria Embankment with his improved scarifier to a depth of 8 inches, and his machines will be working there for the next few weeks, so a good opportunity will be afforded of inspecting

them at work, as drawn by traction engine or ordinary steam roller.

A STAINED-GLASS memorial window has been erected in Slebech Church, South Wales. The subject is *Peace, be Still*. It was presented by Sir Charles Philipps, Bart., and Lady Philipps, of Picton Castle, and was executed by Messrs. Alex. Gibbs & Co., of 10 Bloomsbury Street, London, W.C.

VARIETIES.

MR. H. M. HOWE, who is to receive the Bessemer Medal from the Iron and Steel Institute, is the third American selected for the distinction.

MANY of our readers will be glad to know that a European edition of the excellent American *Engineering Magazine*, from which we have given occasional extracts, is published by Mr. George Tucker, 1, 2 and 3 Salisbury Court, Fleet Street, E.C. It is well deserving of acquisition.

MR. SQUAREY has awarded the sum of 7,132*l.* to the Dorking Charity Trustees as the amount to be paid by the Tunbridge Wells Corporation for about fifty acres of land required for sewage utilisation purposes. Originally the claim was about 11,600*l.*

THE Meisenbach Company, Limited, offer 20*l.* in prizes for the three best displayed specimens of an advertisement of their work. It will be confined to printers.

THE QUESTION OF BETTERMENT.

AT the annual meeting of the Association of Municipal Corporations, the president, Sir A. Rollit, M.P., in the course of his address referred to recent action concerning the question of "Betterment." He said that a committee of the Association had been appointed to discuss that difficult question, and had prepared and presented two reports—a majority report in favour of betterment, and a minority report accepting the principle of betterment, but pointing out certain modifications that ought to be observed with regard to its application. That principle was that public improvements effected by the community ought to be available for the benefit of the community, and not primarily, as in the past, for the benefit of individuals; though, on the other hand, the rights

of individuals ought to be protected. He did not hesitate to say that, owing to the preference given in the past to individuals rather than to the community and to the cost and difficulty of assessing compensation in the case of public improvements, those improvements had been greatly retarded, and that as to railways and other works a heavy public burden and debt had been caused by the high charges that had been incurred with regard to such improvements. Then there was the question of worsement—the injustice of requiring payment for betterment and not recognising compensation for worsement. Ultimately the Council took what he thought was an impartial and wise course in recognising the arguments of both reports and postponing their reception and adoption until more experience had been obtained with regard to the working of the principle of betterment in the various localities, and until it had been ascertained whether it was not possible to so amend existing statutes dealing with the question of compensation for improvements—the Land Clauses Acts, for instance—as to materially minimise the necessity for introducing any new principle by widening the scope of these existing Acts so as to provide both for betterment and worsement. There was no doubt that hitherto compensation had been far in excess of what just requirements rendered necessary. In juries and arbitrations they had to deal with tribunals that in many cases were marked by an unfortunate degree of uncertainty, and the cost of these proceedings was outrageously disproportionate to the claims involved. Provision should be made on one hand that where public authorities were doing work for the public benefit, the burden should not be wholly cast upon the public, while, on the other hand, private rights, wherever they were invaded, should be protected. He hoped some means of settling the question might be speedily found, so that public improvements should be no longer postponed, and that they might no longer see that a measure embodying the principle should be accepted when proposed by the Corporation of Manchester, but should be rejected when proposed by the London County Council. He believed much would result from a careful inquiry into the experience of the various localities with respect to this question. He had great faith in local action. Sir Albert then referred to the great extension in the powers of local authorities which had taken place in the last few years, and expressed the opinion that a still further extension would be witnessed in the immediate future, though he was sorry to say that he had noticed in Parliament some signs of jealousy of these local authorities.

WATERPROOFING BRICKS.

At the recent meeting of the Australian Association for the Advancement of Science Professor Liversidge read a paper on the "Waterproofing of Bricks and Sandstones with Oils." These experiments were made with the view of ascertaining the length of time that bricks and sandstone are rendered waterproof or protected by oiling. The oils used were the three commonest and most readily obtainable for such purposes, namely, linseed oil, boiled linseed and the crude mineral oil known as "blue oil" used for preserving timber. The weatherings were made upon a flat portion of the laboratory roof fairly exposed to the sun and weather. Good sound machine made bricks were experimented on. The amount of oil and water taken up by the sandstone was very much less than that absorbed by the bricks, although the area of the sandstone cubes was much greater than that exposed by the bricks. Equal amounts of the raw and boiled oils were absorbed; the blue oil, however, was taken up in much greater quantity by both bricks and sandstone, but by the end of twelve months the whole of the 13½ ounces of blue oil had apparently evaporated away, and the brick had returned to its original weight, but those treated with raw and boiled oils remained unchanged. After the second oiling in November, 1890, and exposure for nearly four years and two months, they had practically retained all their oil, inasmuch as they had not lost weight and were also practically impervious to water. It was noticeable that the sandstone cubes treated with raw and boiled oils returned to their original weights, but do not appear to have lost the beneficial effects of the oils, being practically impervious to water.

A second paper by Professor Liversidge treated of the porosity of plasters and cements. An elaborate series of experiments was conducted to test the porosity of various plasters and cements. The trials were in all cases made upon slabs prepared by a skilled plasterer, 6 inches square by ½ inch thick, and finished off on one surface in the usual way for walls, the other surface being as left by the board on which the plaster was worked. The slabs consisted of No. 1, ordinary plaster; No. 2, Keene's cement; No. 3, a mixture of half Portland cement and half sand; No. 4, Portland cement. The Professor summed up his conclusions as follows:—From the experiments Keene's cement appears to be the best, on the whole, for indoor work; but it is not adapted for outdoor use unless painted, since it is to a certain extent soluble in water. It takes up less water, less organic matter, as represented by the glue, than others, and practically no dust. Further, it is

more resistant to the action of crystallising sodium sulphate; but Portland cement, if painted, would be even superior to it on account of its greater hardness and durability.

THE ALBERT HALL LAND.

THE board of management of the Royal Commission for the Exhibition of 1851 have caused the following letter to be addressed to the Official Receiver in companies' liquidation, with reference to portions of the Commissioners' estate formerly let to Mr. George Newman and Mr. Steel:—

18 Victoria Street, Westminster: March 21, 1895.

Sir,—I am directed by the board of management of Her Majesty's Commissioners for the Exhibition of 1851 to acknowledge the receipt of your letter of the 16th inst., in which, by direction of the judge, you forwarded for the information of the Commissioners copies of two statements made by Mr. Steel with reference to certain building agreements granted by the Commissioners in respect of land behind the Albert Hall and in Queen's Gate, and you intimated that the judge considers the circumstances under which the agreements were granted should be at once inquired into by the Commissioners.

The board desire, on the part of the Commissioners, to convey to the judge their thanks for the trouble he has taken in causing the papers to be forwarded to them.

The board of management had previously had their attention drawn to some remarks made by Lord Halsbury in delivering judgment in the Court of Appeal on the 14th instant on the hearing of an application made in the matter of George Newman & Company, Limited.

The board, after several preliminary meetings, held a special meeting on the 20th instant to investigate both the subjects referred to above. They have thoroughly examined the minutes and proceedings of the Commissioners and the correspondence which passed with the Commissioners and through their office. They have obtained from the solicitor and the surveyor of the Commissioners reports on the part which those gentlemen took in the transactions; they have had those gentlemen before them and have examined them. They have also examined their permanent officials.

The board are not themselves able to do more than this. They cannot summon before them the person who, according to the remarks of Lord Halsbury, has alleged or insinuated that, in order to obtain from the Commissioners what is called

the Albert Hall land, it was necessary to bribe different persons, nor the persons alleged to be connected with him, nor Mr. Steel, who in the papers forwarded by you refers to certain transactions with the surveyor and the solicitor of the Commissioners.

The suggestion, if any, contained in these statements of Mr. Steel seems to be that two parcels of land leased to Mr. Newman and Mr. Steel were given, "through private influence" exerted on the surveyor, on lower terms than the market value, and that they were then sold by them for large sums to other persons.

The Commissioners, having had very large experience in leasing land both to Government and to private individuals from the year 1857 to the present time, are satisfied that the plots of land leased to Mr. Newman and Mr. Steel were let at the proper market value in 1889.

Except a small piece of land sold by Mr. Steel to a Mr. Walker, under special circumstances, at an enhanced price of about 10 per cent.; and another piece sold by the Commissioners since resuming possession of it, at an enhanced price of 5 per cent., all the land has come back into the hands of the Commissioners by the failure of the conditions of the building agreements, and although tenders have been invited to let the land the Commissioners have as yet been unable to get the land leased on terms equal to those which they obtained from Mr. Newman and Mr. Steel.

So far as the board of management have been able to inquire into the circumstances they are satisfied that their officers had no knowledge of or participation whatever in the transactions which Mr. Sarl (the original applicant for the land), Mr. Newman and Mr. Steel appear to have had in selling their contracts for large sums, and they have passed a resolution to that effect, which I append.

But they hope the inquiry will not rest here, and they offer to give every assistance in their power to yourself or to the judge at whose instance you have written, not only by production of their minutes and records, but also by tendering the evidence of their officers, and if desired of the Commissioners themselves, to enable you to obtain the fullest information as to these transactions. The Commissioners will also be ready to be represented by counsel at this further inquiry should this be desired.—I am, sir, your obedient servant,

ARTHUR ELLIS, Major-General, Secretary.

To S. Wheeler, Esq., Department of the Official Receiver in Companies Liquidation, 33 Carey Street, Lincoln's Inn.

Copy of Resolution of the Board of Management,
March 20, 1895.

It was moved by Lord Thring, seconded by Mr. Childers, and resolved as follows:—

"The board of management have had before them the letter from the Official Receiver and the judgment of Lord Halsbury relating to building agreements made by the Commissioners with George Newman and T. J. Steel, and have examined their paid officers in regard to the transactions as disclosed in the evidence before the Court of Appeal and in the depositions forwarded to the Commissioners by the Official Receiver.

"The board are thoroughly satisfied that their officers acted with perfect integrity and for the interests of the Royal Commission, and that they had no knowledge of, or connection direct or indirect with, the transactions for the sale of the original building contract of the Commissioners for the sum of 16,000*l.* or 26,000*l.*, referred to in the evidence."

GLASGOW INSTITUTE OF MEASURERS.

A MEETING of the council of the Institute was held on Monday afternoon, Mr. J. H. Ramsey, president, in the chair. The Secretary submitted communications from the Associations of Master Masons and Master Brickbuilders regarding schedules prepared by Mr. W. H. Dinsmore, a member of this Institute, for tenements in Kirk Street, Calton, proposed to be erected by the City Improvement Trust, and North Kelvinside School, for the School Board of Maryhill, complaining that these schedules had not been prepared in accordance with the "Glasgow Mode of Measurement for Masonwork, 1885," and the "Glasgow Mode of Measurement for Brickwork, 1894." The schedule for tenements, Kirk Street, having been examined, it was found that a serious departure from the standard mode of measurement had been made in its preparation, but a letter had been received from Mr. Dinsmore intimating his intention hereafter to measure his work in accordance with the modes authorised by this Institute and the other Associations concerned.

With regard to the schedule for the school at Kelvinside the council were gratified to learn from the Secretary of

the Master Masons' Association that at a meeting of representatives of the Maryhill School Board and the Master Masons' Association with the architect and Mr. Dinsmore, the matters complained of had been adjusted in accordance with the standard modes of measurement. In view of the assurance given by Mr. Dinsmore in the letter referred to, the council deemed it unnecessary to take any further action in the matter.

NEW ASSEMBLY ROOMS FOR BIRMINGHAM.

It has often been said, says the *Birmingham Daily Post*, that although Birmingham is abundantly provided with public buildings which are an ornament to the city, it is very badly off for habitations of a reasonable size, which not only afford facilities for meetings and entertainments, but can be utilised with comfort and effect on the occasion of more festive gatherings of a public or private character. The Masonic Hall and the Exchange Rooms satisfy requirements to a certain extent, and the Edgbaston Assembly Rooms were erected to meet a more fashionable demand; but what is really necessary, in the opinion of most people, is a building in a central situation which will combine all the advantages to be found in the establishments mentioned. And it is in order to secure this desideratum that steps are being taken by Messrs. Henry & James Draysey to erect at the corner of Hurst Street and Inge Street a pile of buildings to be known as the City Assembly Rooms. Hurst Street is scarcely a locality in which one would look for a prominent public building, but it certainly possesses the merit of being central and easy of access from all parts of the city.

Plans of the new buildings have been prepared by Messrs. Essex, Nicol & Goodman, architects, Newhall Street, and from these it is evident that the City Assembly Rooms will contain the largest ballroom in Birmingham. The block is to have a frontage of 56 feet 6 inches to Hurst Street and 156 feet to Inge Street, and the total height will be 43 feet. The building itself will be of an ornate description, designed in the Spanish Renaissance style, and erected of red brick and buff terra-cotta. The principal entrance in Hurst Street, which is to be sheltered by a glass verandah overhanging the pavement, will be surmounted by an octagonal tower 100 feet high, and terminating with a lantern and Moresque dome. Facing the

street there are to be three lock-up shops with basement warehouses, the former being ornamented with terra-cotta arches. The elevation towards Inge Street is to be carried out in the same style, but of a plainer description, the height of the main building in the thoroughfare being 58 feet. The principal entrance in Hurst Street will lead into a vestibule, and then a large hall, 28 feet by 25 feet. From this apartment a staircase is to give access to the ballroom and drawing-rooms on the first floor. The spacious ballroom, with an ornamental open-timbered roof, is to be 75 feet long, 41 feet wide and 28 feet high. At one end will be a stage, with accommodation for theatrical and vocal artistes. There are to be two drawing-rooms, one running parallel with the ballroom and the other overlooking the street. The former apartment will be 41 feet by 24 feet, and the latter, lighted by terra-cotta windows, and separated from the ballroom by a promenade surrounding the staircase, is to be 54 feet by 25 feet. Under the ballroom on the ground floor, and exactly the same size in length and width, will be a room 16 feet high, which can be made available as a supper-room on the occasion of a ball, or it can be used for banquets, bazaars, public meetings, auctions, &c. By the side of this room, and consequently underneath the drawing-room, will be an apartment of smaller dimensions, affording adequate facilities for the holding of private or semi-public parties. In the rear of the supper-room the culinary department has been completely arranged. A second entrance is provided from Inge Street, and this will have the advantage of enabling the lessee to let the ground-floor rooms independently of the ballroom suite above. The cloak-room accommodation and the general accessories have been carefully supervised and the structural arrangements have been so contrived that two entertainments can proceed concurrently without interference with each other. According to the plans every attention has been paid to the all-important subject of the safety of the audiences. In addition to the ordinary staircases and entrances emergency exits have been provided in the principal rooms, a consideration which should inspire confidence in the management. One great feature of the scheme is the fact that the building will be capable of accommodating large or small parties. The whole of the rooms may be engaged, and 400 or 500 persons can comfortably be accommodated at a dance and supper, or if the party is a small one of say about one hundred persons, one of the drawing-rooms, which has a gallery for the musicians and ample space for a refreshment buffet, can be secured

as a ballroom. In any case, however, absolute privacy is insured, because the structure is so designed that the rooms engaged may be easily isolated from the other portions of the building. A fireproof floor is to be laid down over the lock-up shops and in the culinary department, and the whole of the premises will be heated and ventilated in the most approved manner; all the modern improvements will be adopted in the construction and fitting up of the assembly rooms. They will, moreover, be illuminated by electricity, and the arc lamp which it is proposed to place in the lantern will be a prominent feature of the tower. The internal decoration of the building will be in harmony with the architectural treatment of the exterior, and executed in Parian cement. The ballroom is to be made especially attractive, with its ornamental pilasters and proscenium front, the general scheme of colour being cream and gold. The total cost of the erection of the building and the furnishing and fitting of the rooms, &c., will amount to upwards of 11,000*l.* The contract for the building is to be placed in a day or two, and the work, which will be commenced forthwith, is expected to be completed in the autumn.

THE QUANTITIES QUESTION IN GLASGOW.

A MEETING of the Glasgow Town Council was held on March 22, when the subject of the schedules of quantities for labourers' dwellings which were rejected by the builders was introduced.

Mr. Nelson asked how many tenders were received for the brick and stonework of a block of labourers' dwellings in Kirk Street, Carlton.

Bailie Chisholm said one tender was received and passed by the committee. He understood from Mr. Bowers that another came in too late to be received.

Mr. Nelson said he understood that when tenders were sent out for this contract, the measurer departed from the usual course of measuring buildings, and went back to the old use and wont in existence in Glasgow three years ago. This was the first instance during the last three years in which the Improvement Trust had made any departure from the method adopted by architects, measurers and contractors in Glasgow. Seeing that there was only one tender, he thought it would be right for the sub-committee to take the subject back. He did not think the Corporation wanted to get 13 inches to the foot, nor

that they should get only 11 inches to the foot. It would be unfair for the Corporation to seek to get a cheap job at the cost of a contractor. Before the measurements were adopted by the measurers, architects and contractors in Glasgow, almost every job of importance had to be sent to arbitrators. To avoid this, and in order that measurers and parties employing them, and contractors, might know exactly what was wanted, this scheme was adopted three years ago. He would be very sorry that the Corporation should depart from it without some good reason being assigned.

Mr. Donald Hamilton corroborated all Mr. Nelson's statements. The code of measurement had been adopted generally, and he did not see why the Corporation should depart from that which was so well recognised.

Mr. Robert Anderson said as one interested in contracting he had had a considerable deal to do with the formulating of the Glasgow code of measurement. Previously to its adoption every measurer was a law unto himself as to how he would measure and what he would exclude or include. It was to avoid this confusion that the code was drawn up. He thought that the committee or the engineer should be able to show very strong reasons before it was agreed to depart from the recognised practice. The fact that all the schedules for brick-building and masonry had been returned showed the sense of injustice under which the brick-builders and masons lay.

Mr. Steele said there was a difference of opinion as to the new code of measurement. There were quite a number of measurers who did not act under it. The reason why it was proposed to make an alteration was that the committee desired to see how far they could go in the direction of supplying dwellings for the working classes at a cheap rate.

A Member: At the expense of the contractors.

Mr. Steele: No.

The Member: At whose expense then?

Mr. Steele, continuing, said he thought it was beneath the dignity of the Building Exchange to make a noise against a small thing like that.

Mr. Robert Anderson stated that the code of measurement was in operation long before the Building Exchange came into operation.

Mr. Steele replied that he was quite aware of this. What he wanted to make plain was the fact that the code of measurement was not adopted by all the measurers. The mode of measurement adopted was stated at the top of each schedule, so that the officers knew the position of matters.

Mr. Robert Anderson said he was quite prepared to prove the fact. The committee were anxious to have the houses opened as soon as possible.

Mr. Battersby asked what difference the new method would make upon the rents of the proposed houses.

Mr. Shearer, apart from the dispute between the measurers and the Corporation, asked whether it was in the interest of the ratepayers that the Corporation should accept an offer without knowing whether it was in excess of what the amount ought to be. On that ground alone he thought it reasonable that the matter should be sent back for further consideration.

Mr. D. M. Stevenson held that when an offerer tendered in accordance with the conditions that had been laid down, and was in all respects a proper contractor, they ought to give him the preference if he was the cheapest. He did not think they should allow outsiders to alter their conditions after they had been laid down.

Mr. King asked if they were going to throw overboard a contractor who offered according to their conditions for the sake of others who might boycott them at any time.

Mr. Martin said that he had only learned that day that there was only one offer.

Mr. J. R. Paton urged that the minute should be taken back. He thought the Council sought to do everything honestly and honourably. If this work was done it must be paid for; and if the new mode was for the sake of getting it done cheaper, it must be at the expense of the contractors.

Mr. Campbell said that the Improvement Trust was taking upon itself to create a novelty, and to interfere with use and wont upon a very important matter affecting the interests of the community at large.

Mr. Willock said that had the representation come from an employees' association, instead of an employers' association, it would not have been considered.

Mr. Nelson said the saving that would be effected by the new method amounted to only 16*l.* 10*s.*

The Lord Provost said he understood that the schedules had been issued entirely on Mr. McDonald's responsibility, and not on the responsibility of any member of the committee.

Bailie Chisholm thanked the Lord Provost for making plain the position of the Improvement Trust Committee in this matter. The committee had not the remotest responsibility for it, and were in the utmost ignorance of the fact that Mr. McDonald had issued the specifications in the form he had done. Bailie Chisholm proceeded to explain that as a result

Established 1860.

of a conference between the health committee and the Improvement Trust, Mr. M'Donald was instructed to prepare plans for houses on a little piece of ground belonging to the Trust in Kirk Street, Carlton, and which they thought would be suitable for experimental tenements. Mr. M'Donald was instructed to produce the very best class of cheap houses, and with these instructions he thought on this method. Mr. M'Donald took the whole responsibility on himself. The conditions were plainly stated at the top of the specification. The one offer that had been received was less than the amount that Mr. M'Donald had anticipated, and it was therefore plain that they were not suffering because they had been boycotted by the other contractors. Mr. M'Donald was in London on official business, and was consequently not able to be present; but he had written a letter explaining the matter, and repudiating the statements that had been made by the Building Exchange committee. Bailie Chisholm concluded by stating that the matter involved was a very trivial experiment. If it succeeded they would be encouraged to do something on a larger scale. They would be able to compare the results of the old methods with those of the new, and do that which in their experience seemed best.

Mr. Campbell, in the light of the clear statement of the case by Bailie Chisholm, appealed to Mr. Nelson to withdraw his amendment. Personally he was quite satisfied.

Mr. Nelson declined to withdraw.

On a division the minutes were adopted by 49 to 11.

THE WEATHERING OF BUILDING STONE.

(Concluded from last week.)

THE action of oxygen as a weathering agent is important in respect to a few minerals only. Certain sulphides, especially the brassy yellow mineral iron pyrites, are changed by oxygen in the presence of moisture into sulphates and finally into oxides. Granites, marbles and other crystalline rocks containing these minerals may be weakened by their weathering out, and are stained an ugly brown by the hydrous oxide formed, so as to be quite disfigured. This change is less important in the sandstones, though even then the change of colours may be disagreeable. Many stones used in the Parliament Buildings at Ottawa illustrate this, the dark brown smear having some-time run down on to the blocks below. Stones rich in magnetite,

such as diabase, sometimes used as black granite, may be acted on in a different way. The mineral magnetite consists of the sesquioxide of iron combined with the monoxide. The latter portion may weather into hydrous sesquioxide, giving brown stains, and sometimes causing the rock to crumble. A similar effect, though less important, has been observed in some massive rocks containing large amounts of silicates rich in iron, hornblende or augite.

Water charged with carbonic acid is a very efficient weathering agent and has some action on most minerals, except quartz. In the granite of the Thousand Islands large blocks of quartzite are sometimes found, and as a rule the quartzite projects sharply an inch or so above the granite, showing the amount of weathering and degradation since the time some thousands of years ago when all was planed smooth by glaciers.

In the case of granite and other massive crystalline rocks this weathering consists in the change of the felspar into clayey substances and of the mica and hornblende into impure clay, oxides of iron, &c. The quartz grains are loosened in this way and are washed off by rain action, leaving fresh surfaces exposed. Without the help of frost it is probable that this variety of weathering would go on very slowly. Granite monuments in our cemeteries seem but little affected even after standing a number of years, though they gradually lose their polish and grow rough.

Limestones are more easily attacked. If pure they are slowly dissolved, but keep a tolerably smooth surface. If impure, as they generally are, the particles of sand and clay are insoluble and form a crust on the surface. With this the soot of city atmospheres combines to change the original colour into a dingy black. Limestones with large fossils soon become unsightly on dressed surfaces from the projection of the fossils. Marbles or crystalline limestones are very readily acted on. A study of marble tombstones in our cemeteries shows that even a few years' exposure removes the polish, except on parts that are protected. Every marble slab which I have examined, bearing a date of twenty years or more ago, has completely lost its polish on all exposed parts, has turned grey in colour and is so friable that one can easily rub off particles with the finger. It is quite evident that marble is entirely unsuited for outdoor use in the climate of Toronto.

Sandstones differ greatly among themselves in their liability to weather, hard quartzitic ones being almost unattacked, while porous, loose-textured sandstones crumble sometimes very rapidly. These differences depend chiefly on the character

and amount of the cement which holds the particles together. A clayey cement is the worst, since it readily absorbs moisture and is crumbled by the action of frost. Such sandstones are seductively easy to work, so that builders are tempted to use them for carvings, but often the storms of a single winter will round the edges and spoil the sharpness of such carvings, particularly on exposed corners of buildings.

A calcareous or lime cement, though better than clay, is comparatively easily dissolved by rain water charged with carbonic acid, and still more easily by water containing traces of sulphurous or sulphuric acid, such as may frequently be found in the air of cities. Carbonate of iron is another, though rarer cement, which is easily soluble. The red anhydrous oxide of iron resists solution very well, the brown hydrous is less resistant. The most permanent cement of all is a silicious one, which is practically unaffected by rain charged with an ordinary solvent; but unluckily such sandstones are so hard to work, and usually of such poor colours, that builders rarely employ them.

A rather fine-grained grey sandstone frequently used in our cemeteries has turned darker grey, but resists weathering often admirably. Horizontal slabs fifty years old are not at all friable and still retain their inscriptions, though somewhat encrusted with dirt and lichens. A yellowish sandstone has not stood as well, and after thirty-five years in one instance has weathered so as to be quite illegible.

The presence of clay spots in sandstone is most injurious to the appearance, since they weather out and leave ugly holes, sometimes not standing even a single winter. The filling of the holes with powdered sandstone and shellac renders the stone presentable, but only for a short time. Still worse is the presence of clayey layers between the laminae either of sandstone or limestone. The clay rapidly weathers out, spoiling the dressed face of the stone and in time weakening the whole wall.

The hardening of certain limestones and sandstones after quarrying is an interesting effect of the action of the air, though not properly included under weathering. It appears to be due to the drying-out of the quarry water with which the stone was soaked. As it dries out, all the substances which it held in solution, such as lime and silica, are deposited, hardening the surface of the block. If once this hardened skin is removed, however, no amount of wetting with pure water will renew it.

Thus far we have considered the action of the weather in decomposing and dissolving part or all of the constituents of a

building stone, injuring its strength and durability; but there is another action of some importance to the architect as an artist, that is, the slow change of colour which most varieties of stone undergo after taking their place in a building. This may be called the mellowing touch of time as contrasted with his gnawing tooth, and from the artistic side an architect's work, like a rich wine, may ripen and improve with years.

Most of these colour changes are the result of slow oxidation. Some dark grey or bluish limestones, like those of Kingston, contain bituminous matter from the multitude of fossil organisms that died to form these beds of rock. This colour is slowly lost by oxidation, and the surface of the stone gradually reaches the true colour of the limestone, a pale grey, sometimes even suggesting marble. As a general rule such changes of colour are due to oxidation of iron compounds from the monoxide, which is green or black as a rule, to the sesquioxide, which is yellow or brown or red. The general effect then is to change the colour from cool greenish greys to warmer yellows or browns. An old marble statue, cold white in the beginning, becomes yellowed like old ivory with the lapse of time; but this change may be due partly to the action of dust and soot in cities. Many whitish or grey limestones yellow in a somewhat similar way. Grey or greenish sandstones generally take on a yellow or brown tone in time. In many cases this change of colour is a distinct improvement, especially where stones of different colours which do not quite harmonise have been used together.

Of course in cities burning much soft coal, colour is of no importance, since all colours are presently shrouded in an impartial pall of sooty grey or dingy black.

In towns burning mostly hard coal, like our own Toronto, with its usually clear skies and clean atmosphere, the colour scheme and the changes which time will give rise to should be carefully considered, more so than they are at present.

In choosing a building stone which has not been thoroughly tested by use one may very easily make mistakes. The colour, the texture, the power to resist crushing strain, as the stone comes from the quarry, may all be greatly modified by weathering. The amount of moisture which the stone will absorb, the chemical constitution and the mineral composition, as shown under the microscope, all afford data by which to judge of its lasting qualities; but perhaps the best test of all is to examine the neighbourhood of the quarry and see what effect weathering has had upon loose blocks or exposed ledges of similar stone. In any case, architects in choosing stone for

LIGHTHOUSE ILLUMINANTS.

A MEETING of the Shipmasters' Society was held on the 19th inst. at the London Chamber of Commerce, when a paper was read by Mr. John R. Wigham on "Lighthouse Illuminants." He alluded to the origin of the use of gas for lighthouses, remarking that it was first employed at the Bailey Lighthouse, near Dublin, in 1865. Up to that time there were no means by which a lighthouse-keeper could increase the power of his light in thick weather. It occurred to him (Mr. Wigham) that such a plan would be of much value to mariners, and the burner which he constructed was used in all the lighthouses in which his gas system was adopted. The burner had six powers, which might be added according to the state of the weather. A light-keeper could thus almost instantaneously increase his light in thick weather, and when the necessity had passed again reduce his light to its ordinary power. Mineral oil was the illuminant now used in most lighthouses. Following the example of the gas-burner, the larger sizes of the oil lamps were provided with a means by which the light in thick weather could be increased. The lecturer afterwards referred to the electric light, which, he said, he had not found useful in penetrating fogs, and he quoted the testimony of mariners to this effect. He exhibited a model of what he called the "giant lens," which was made by Barbier & Co., of Paris, and which he described as by far the most important advance that had been made in lighthouse lerticular apparatus since the time of Fresnel. The most recent improvement which he had suggested in lighthouse illumination was what he had called the "continuous pulsating light," by which, he said, all the power of the lenses of revolving dioptric apparatus could be secured to the mariner continuously. At present the light from such apparatus was intermittent, but under the new arrangement the light would be permanent, and would also present a peculiar pulsating appearance, which could not possibly be mistaken for any other light. In addition to all the present known appliances for strengthening the power of lighthouse illuminants in foggy weather, he advocated the placing outside on the balcony of every lighthouse and lightship of flaring apparatus of the photogene type, so as to illuminate the fog, and thus

enable mariners to see the effect of the light when they could not see the direct beam of the lighthouse. In the discussion which followed Admiral Colomb alluded to certain experiments which he had made some years ago to determine what effect the size of the light had with regard to its intensity. These experiments were, however, very incomplete; but the new gas—acetylene—promised a great field for use in lighthouses in the system described by the lecturer.

PATENTS.

[This List of Patents is compiled specially for this Journal by Mr. G. H. Rayner, of the firm of Rayner & Co., Consulting Patent Agents, 37 Chancery Lane, London, W.C., from whom all particulars and information relating to Patents may be had gratuitously.]

APPLICATIONS FOR PATENTS.

- 5161. Edwin Verity and Benjamin Banks, for "Improvements in Sliding Ventilators."
- 5171. Thomas William Twyford, for "Improvements in or additions to water-closets or water-closet basins."
- 5274. Samuel Stevens Hellyer, for "Improvements in and connected with lavatory basins and the like."
- 5294. Thomas Innes Grays, for "Improvements in ashpit and other door-fasteners."
- 5396. Julius de Long, for "Improvements in window ventilators."
- 5423. Alfred Henry Cooper, for "Improvements in window sashes."
- 5441. Daniel Dixon, for "Improved ventilating flues for cooking apparatus."
- 5464. William Metcalf, for "Improvements in rain and draught excluders and door-silencers."
- 5465. William Marshall, for "Improvements in the construction of window casements and frames."
- 5534. Herbert Charles Norfolk, for "Improvements in sash windows."

ART PLATES FROM "THE ARCHITECT."

Awarded Gold Medals, International Health Exhibition and Architectural and Building Trades Exhibition (1889).

PROOFS on PLATE PAPER of the following Illustrations which have appeared in "THE ARCHITECT" can now be obtained in a separate form suitable for Framing.

THE MARTYRDOM OF ST. STEPHEN. By E. J. POYNTER, R.A. Size, Forty Inches by Fifteen Inches. Price One Shilling. Free by post, carefully packed inside patent roller, One Shilling and Three Pence.

"AND THE SEA GAVE UP THE DEAD." By Sir FREDERIC LEIGHTON, President of the Royal Academy. A few Proofs of this Fine Art Plate can be obtained (if ordered at once), price Two Shillings each. Free by post, carefully packed inside patent roller, Two Shillings and Two Pence.

THE BANQUET. The well-known and beautiful Chromo-Lithograph by H. STACY MARKS, R.A. Size, Thirty-nine Inches by Fifteen Inches. Price One Shilling. Free by post, carefully packed inside patent roller, One Shilling and Three Pence.

1. AN OFFERING TO CERES. 2. THE EDUCATION OF BACCHUS. 3. MINERVA VISITING THE MUSES. 4. JUDGMENT OF MIDAS. By W. HAMILTON. Size of each plate, Forty Inches by Fifteen Inches. The whole forming a very beautiful Frieze in Bartolozzi Mezzotint. Price per set, Six Shillings on Proof Plate. Free by post, carefully packed inside patent roller, Six Shillings and Six Pence.

THE HISTORY OF JOAN OF ARC. By M. JULES EUGENE LENEVEU. From the Wall Painting in the Panthéon, Paris. Four Pictures on one Plate. 1. Domremi: Inspiration. 2. Orleans: Struggle. 3. Reims: Triumph. 4. Rouen: Martyrdom. Size, Forty Inches by Fifteen Inches, on Proof Plate. Price, Two Shillings. Free by post, carefully packed inside patent roller, Two Shillings and Six Pence.

THE WATERLOO HEROES. By J. P. KNIGHT, R.A. Dedicated, by Special Permission, to VISCOUNT WOLSELEY, K.P., G.C.B. Proofs, price One Shilling each (thin Plate Paper). Proofs (Special), price Two Shillings and Six Pence each (thick Plate Paper). Size Twenty Inches by Thirty-six Inches. Framed and Glazed in Oak, Complete, One Inch, Twelve Shillings each. Ditto, One and a Quarter Inch, Fourteen Shillings each. Ditto, One and a Half Inch, Seventeen Shillings each.

THE TOILERS OF THE DEEP. Two Tinted Ink Photographs. Size, Eighteen and a Half Inches by Thirteen and a Half Inches. Price Two Shillings. Free by post, carefully packed inside patent roller, Two Shillings and Three Pence.

JOHN SELL COTMAN'S PICTURES, lately on Exhibition at the Burlington Fine Arts Club. The Plates are uniform in size, Twenty-one Inches by Fifteen Inches. The Titles are as follows:—1. Rouen from Mount St. Catherine. 2. Breaking the Clod. 3. View in North Wales. 4. Norman Arches. 5. Byland Abbey. 6. Norwich, from the Cromer Road. 7. Dewy Eve. 8. Mousehold Heath. 9. Cader Idris. 10. Castle Eden Dean, Durham. 11. Bamborough Castle. 12. The Interior of Norwich Cathedral. 13. Mountain Pass in the Tyrol. 14. Postwick Grove.

The price of the Set is Twelve Shillings and Six Pence; by post, carefully packed in patent roller, Thirteen Shillings. Kindly order early, as only a limited number of proof copies can be obtained.

May be obtained from all Newsagents, Booksellers, Messrs. W. H. SMITH & SON'S Bookstalls, or from the Publisher, P. A. GILBERT WOOD, 175 Strand, London, W.C.

THE Architect and Contract Reporter.

NEW READING CASE.

To Librarians of the Public Libraries and Reading-rooms.—A new handsome Reading Case can be supplied at a nominal charge of 2s., by post 2s 6d., on early application to the Publisher, 175 Strand, W.C.

SPECIAL NOTICE TO THE TRADE AND OTHERS.

[Extract from a lecture on Architects' Libraries by Professor T. Roger Smith, F.R.I.B.A., at University College, October 10, 1893.]

"Lastly, let me recommend the back volumes of the professional journals. In the course of years all sorts of architectural topics come up in the public press and before the professional societies, and if you hunt through the indexes of these publications when you are seeking for information which eludes you in books, you will often be rewarded."

There has been a considerable demand for the back numbers of *The Architect* during the last three or four months, which we have no doubt has arisen from the remarks made by Professor Roger Smith, as contained in the above quotation; but the consequence has been that our stock of back numbers is getting very low, and consequently, in future, the charge for back numbers of previous date to January 12, 1894, will be 6d. each.

A few of the back volumes may still be had, price 12s. each.

EDITORIAL NOTICES.

The authors of signed articles and papers read in public must necessarily be held responsible for their contents.

No communication can be inserted unless authenticated by the name and address of the writer—not in every case for publication, but as a guarantee of good faith.

Correspondents are requested as much as possible to make their communications brief. The space we can devote to Correspondence will not usually permit our inserting lengthy communications.

ADVERTISEMENT SCALE.

For Two Lines and under (eight words to the line)	£0	2	6
For every Additional Line		0	6
For Quarter Page		2	10 0
For Half Page		4	10 0

"SPHINX" PORTLAND CEMENT.

112 lbs. per bushel. Slow setting; test 1,000 lbs. to 1 1/2 inch; seven days. Fineness, 2,500 meshes to square inch, with less than 10 per cent. residuum. Over 10,000 tons supplied to Cardiff and Hereford Water Works.

Specially adapted for Concrete Floors & Street Paving.

"ECLIPSE" PORTLAND CEMENT.

Quick-setting; test, 8 parts. Standard Testing Sand, 250 lbs. per square inch; 28 days. The finest, most plastic, best sand-carrying and cheapest Cement in the market.

Specially adapted for laying encaustic tiles, making joints in sanitary pipes, internal stucco, concrete foundations, &c.

Samples sufficient for Practical Tests Free. Manufactured by JOHN BOARD & CO., Dunball, Bridgwater.

ESTABLISHED 1844.

NATURAL PORTLAND AND ROMAN CEMENTS, HYDRAULIC BLUE LIAS LIME, Plaster of Paris, Keene's and Parian Cements, Bricks, Roofing Tiles, Drain Pipes, Paving Tiles, Bath Bricks, &c. Railway and water communication.

THE BUILDING EXHIBITION.

IN this number we resume our notices of the principal stalls in the Building Exhibition, which amply represent the industries connected with construction in this country.

The National Accident-Prevention Safety-Window Company showed the National Accident-Prevention safety-windows, which deservedly took a gold medal at the Manchester exhibition of 1894. This system of safety-windows seems the perfection of simplicity, owing to the absence of any more mechanical arrangements than are found in ordinary windows that slide up and down. But for safety purposes while cleaning they open inwards; a metal rod or stay is then applied, keeping the sash at a convenient angle, and removed as soon as the cleaning is effected. One rod will serve for every window and sash in the house, and may then be relegated to the housemaid's sanctum for brooms and other treasures used for carrying out the service of the house. It is a simple process to apply this system to any existing windows. The adoption of this system is now very universal, and it is stated that in one month 10,000 were adopted. The matter of convenience is very important, but what is most important is that safety is secured for the cleaners of windows.

William Hayward & Sons.

This exhibit was in its special department second to none. This firm are manufacturers of wrought-iron entrance gates, palisading, grilles, &c. The designer of the work shown is to

be congratulated on his very ornamental treatment of wrought-iron. Ornamental ironwork is not successful in many cases, because the element of success depends on simplicity, which is not easily achieved. Any amount of elaboration will not give artistic effect to ironwork, such as was seen in the samples shown by William Hayward & Sons at their stand in the Hall. To be elaborate in ornament is comparatively easy to the majority. To gain the highest artistic effects by simplicity is not at all easy, and only a minority succeed. The articles shown included beautifully designed and executed entrance-gates, double or central gates, single gates, grilles for doorways, &c. The effect of the palisading was well shown as fixed on sections of dwarf walling in brickwork and stone coping. These specialties above referred to include several new designs, shown, we believe, for the first time. There are different styles of architecture, and Messrs. Hayward & Sons' designs differ in style accordingly, so as to show what is in harmony with any particular design.

Walter Gibbs.

Mr. Walter Gibbs had a grand assortment of glass decoration. His patent process of amber-staining is claimed to be the best and latest improvement in glass-work, and that it has brought the art of French embossing and brilliant cutting to its highest perfection. It is a harmonious combination of white and gold decoration designed and developed to be principally adaptable for hotels, public buildings, mansions and domestic purposes generally, with equal effect. He had also some beautiful specimens of handpainted mirrors painted on the back of glass, which give them a most brilliant effect; also some specimens of engraved mirrors. His other exhibits consisted of samples of writing for brewers' tablets, fascias, &c., embossed, shaded embossing (double and treble), plain and ornamental lead-glazing in variety. The work seen at this stand was worthy of being shown at any exhibition.

Freeman Bros.

Freeman Bros., of York Road, Battersea, showed samples of their now well-known "grip-joint" lead connections for joining closet-traps and other earthenware nozzles to lead soil and other pipes. These joints have already been subjected to three years' practical tests, and are found to be most thoroughly reliable. By the use, in conjunction with them, of the screwed earthenware nipple which the firm supply at a very nominal price, any pedestal or other closet that is in stock can be used with the "grip-joints." They also showed their patent adjust-

SHOWROOMS AND MANUFACTORY:—

55 and 56 HIGH HOLBORN, LONDON.

able pedestal closets, which, though made on the latest approved lines sectionally, are also so designed as to be adaptable for use under the very frequent awkward conditions that pertain to closet-fixing; for instance, in event of the position of the outside soil pipe making it desirable that the outgo from closet-trap should be even at right angles relatively to the basin inlet, compliance with this stringent and most usual requirement is perfectly possible by using this closet; and consequently, even though but one of the type is kept in stock, the plumber is ready for any exigency as to fitness for position. Their latest sanitary specialty, viz lead-lined cast-iron junction-pieces, to afford facilities for making connections between lead branch soil pipes, sink wastes, anti-siphon pipes, and the like, and cast-iron outer pipes, in a mechanical and thoroughly workmanlike manner,

will further be found a most economical arrangement, in comparison to the use of brass ferrules, thimbles, &c. A combination of these specialties was well represented by the firm's "Triple Alliance," a block of which we display with this notice. Altogether the exhibit had much to commend it, and our readers will do well to write for price list.

Also were shown, for Messrs. William Hepton & Son, of Hunslet Lane, Leeds, their special registered corrugated copper cylinders for domestic hot-water purposes, which are constructed with a view to securing cheapness with efficiency. It is well known in the trade that the system of loading cylinders only reduces the price per lb., but the cost of such a cylinder is greater

than that charged for corrugated cylinders, which are sold at so much each and guaranteed to stand a definite pressure; by specifying you save money and secure a pure cylinder to stand pressure required. The cylinders are well finished, with bright polished tops, and fitted with cap and lining unions, with iron thread, which greatly facilitate fixing. This firm also exhibit some seamless corrugated copper cylinders, which are exceedingly well made, the bodies being one piece of copper without any join, and from appearance should command a ready sale. Their London representative, Mr. W. E. Morris, informs us that these cylinders are gradually finding favour with the trade, and that the prices compare favourably with galvanised iron cylinders, costing but a trifle more; but copper cylinders have several points in their favour, principally, that they hold the heat much better, do not discolour the water, last from fifteen to twenty years, and are of value when taken out.

Potter & Co., Limited.

Messrs. Potter & Co., Limited, of Victoria Street, showed their fireproof floor construction, a combination of steel and concrete lintels and beams. The "A" floor, a section of which was shown, weighed 24 lbs. per foot super, and is up to loading with 450 lbs. super per foot without injury. Floor "B," a section of which was also shown, was similar, with the exception that it is without ceiling. Their "C" floor, which can be executed as quickly as wood floor, also being quite dry, is ready for immediate use, and the ceiling affords considerable scope for artistic treatment, and the weight is only 16 lbs. per foot super. Floor "D" is of the lightest possible description for a fire-resisting floor, is similar to floor "C," but the ceiling is omitted, and it is not sound-proof. The weight is 13 lbs. per foot super, but the floor-slabs have stood a test up to 10 cwt. per foot super. A feature of this system is that it is very inexpensive.

Candy & Co., Limited,

of South Devon (London office, Queen Victoria Street), showed a fine collection in various specimens of sanitary stone-ware, white and coloured glazed bricks, salt glazed bricks, facing and engineering bricks, architectural terra-cotta, granite vitrified paving bricks, &c., a feature of their productions being that they are acid-proof, in addition to the numerous other merits.

Moule's Patent Earth Closet Company, Limited.

This company showed their system, which is used in so many districts all over the country. The sanitary principle which

characterises the Moule's closet is the same, but a great variety was shown in the mode of application to so numerous requirements. To mention a few, ranges of closets for schools, workhouses and the like were provided and the models shown. There were portable closets according to different needs, and they were also shown fitted up in high-class style for the use of cottages, farms, &c.

The Sanitary Bath Company, Limited,

of 12 Miller Street, Camden Town, showed in some five or six baths handsome examples of well-finished work in their patent steel-clad copper and patent enamelled steel baths and fittings, which are already known in the market.

H. & A. Hooydonk

showed samples of the beautiful decorations in Hooydonk's patent Dakoria as applied for mantelpieces, wall-panels, dados, friezes, pilasters, &c. At night the stand was illuminated by electric light furnished by Mr. F. Hooydonk, electrical engineer.

The Fireproof Construction Co.

Most excellent samples were shown as demonstrations of the value of this company's hygienic fireproof partitions, specimens being on view showing its principle. The hygienic fireproof cement is, in addition, a cement to be recommended. There are many advantages in the hygienic construction, some of them being the following:—The partitions are in themselves less than one-fifth the weight of $4\frac{1}{2}$ brickwork, but the interlacing binding procured by their system of clamping renders them perfectly self-supporting from wall to wall, so that if necessary any portion of the wall may be cut out, which is done simply by sawing, for doorways, &c., without in the least degree weakening the partition. This property also avoids the necessity of using an iron joist to carry the wall, as the work can be built straight on to the wood floor. The absence of any woodwork in this structure should be a recommendation for its adoption, as the inconvenience of cracked walls and dry rot are thus entirely obviated, as also the open space which in a lath-and-plaster partitioning makes such a grand receptacle for vermin and dirt. The partitions are also sound-resisting, and have been used in musical cubicles to stop the noise of piano practice with great success. The same methods of construction as are applicable to the walls of buildings are also used for the fireproofing of wooden joist floors.

Joseph Kaye & Sons, Limited,

were well represented at their stand by their ingenious and useful appliances, which we have so often referred to. Mr. Kaye has distinguished himself in invention, and had a good exhibit of his locks and bolts. Kaye's patent automatic wedge-lock for broughams, as adopted by Lord Suffolk for H.R.H. the Prince of Wales's broughams, and highly approved of, was shown. This lock wedges the door fast by easy closing, and so saves banging the doors to. The handles plainly indicate the door fast or not fast, which is of importance. Kaye's patent automatic wedge-lock is adopted in other forms by railway companies for all kinds of doors on carriages to prevent rattling, and with the patent automatic safety catch it is the greatest safety, with inside handles, and will be a great saving of carriage doors, and require no attention of guards or porters. It will be greatly to the advantage of all railway companies and the travelling public to adopt them on all kinds of carriage doors, as no one can get out of a train only purposely. They also have made above 25,000 of another lock for the Great Northern Railway, besides other railways, which has great security and lasting qualities, some of which have been in use nine years and are still perfect.

John F. Simmance,

of Hatton Garden and St. John Street Road, E.C., showed his patent exit valve system of ventilation, as adopted on the White Star line of steamers, H.M. torpedo-boats, &c., adapted for drain (foot) ventilation, and other purposes, insuring the proper direction of currents of air. It is well contrived for the purpose, to be as independent of currents of air and draughts as any system can be. Since its first introduction it seems to have further improved and simplified, with the result that prices are quoted at very cheap rates, and great attention appears to have been given to a sound construction of the valves. Drain-aerating inlet valves were also shown, carried out on the same effective principles.

David Kirkaldy & Son.

The stand showed what may be termed a "museum," and of one of the most interesting kind in the practical demonstration of the effects of testing materials used for building purposes. Extra interest was added from the accepted reputation of this firm everywhere as the most reliable of experts. The margin of safety stresses, both thrusting and bending, is well

ART PLATES FROM "THE ARCHITECT."

Awarded Gold Medals, International Health Exhibition and Architectural and Building Trades Exhibition (1889).

PROOFS on PLATE PAPER of the following Illustrations which have appeared in "THE ARCHITECT" can now be obtained in a separate form suitable for Framing.

THE MARTYRDOM OF ST. STEPHEN. By E. J. POYNTER, R.A. Size, Forty Inches by Fifteen Inches. -Price One Shilling. Free by post, carefully packed inside patent roller, One Shilling and Three Pence.

"AND THE SEA GAVE UP THE DEAD." By Sir FREDERIC LEIGHTON, President of the Royal Academy. A few Proof of this Fine Art Plate can be obtained (if ordered at once), price Two Shillings each. Free by post, carefully packed inside patent roller Two Shillings and Two Pence.

THE BANQUET. The well-known and beautiful Chromo-Lithograph by H. STACY MARKS, R.A. Size, Thirty-nine Inches by Fifteen Inches. Price One Shilling. Free by post, carefully packed inside patent roller, One Shilling and Three Pence.

1. AN OFFERING TO CERES. 2. THE EDUCATION OF BACCHUS. 3. MINERVA VISITING THE MUSES. 4. JUDGMENT OF MIDAS. By W. HAMILTON. Size of each plate, Forty Inches by Fifteen Inches. The whole forming a very beautiful Frieze in Bartolozzi Mezzotint. Price per set, Six Shillings on Proof Plate. Free by post, carefully packed inside patent roller, Six Shillings and Six Pence.

THE HISTORY OF JOAN OF ARC. By M. JULES EUGENE LENEVEU. From the Wall Painting in the Panthéon, Paris. Four Pictures on one Plate. 1. Domremi: Inspiration. 2. Orleans: Struggle. 3. Reims: Triumph. 4. Rouen: Martyrdom. Size, Forty Inches by Fifteen Inches, on Proof Plate. Price, Two Shillings. Free by post, carefully packed inside patent roller, Two Shillings and Six Pence.

THE WATERLOO HEROES. By J. P. KNIGHT, R.A. Dedicated, by Special Permission, to VISCOUNT WOLSELEY, K.P., G.C.B. Proofs, price One Shilling each (thin Plate Paper). Proofs (Special), price Two Shillings and Six Pence each (thick Plate Paper). Size Twenty Inches by Thirty-six Inches. Framed and Glazed in Oak, Complete, One Inch, Twelve Shillings each. Ditto, One and a Quarter Inch, Fourteen Shillings each. Ditto, One and a Half Inch, Seventeen Shillings each.

THE TOILERS OF THE DEEP. Two Tinted Ink Photographs. Size, Eighteen and a Half Inches by Thirteen and a Half Inches. Price Two Shillings. Free by post, carefully packed inside patent roller, Two Shillings and Three Pence.

JOHN SELL COTMAN'S PICTURES, lately on Exhibition at the Burlington Fine Arts Club. The Plates are uniform in size Twenty-one Inches by Fifteen Inches. The Titles are as follows:—1. Rouen from Mount St. Catherine. 2. Breaking the Clod. 3. View in North Wales. 4. Norman Arches. 5. Byland Abbey. 6. Norwich, from the Cromer Road. 7. Dewy Eve. 8. Mousehold Heath. 9. Cader Idris. 10. Castle Eden Dean, Durham. 11. Bamborough Castle. 12. The Interior of Norwich Cathedral. 13. Mountain Pass in the Tyrol. 14. Postwick Grove.

The price of the Set is Twelve Shillings and Six Pence; by post, carefully packed in patent roller, Thirteen Shillings. Kindly order early, as only a limited number of proof copies can be obtained.

May be obtained from all Newsagents, Booksellers, Messrs. W. H. SMITH & SON'S Bookstalls, or from the
Publisher, P. A. GILBERT WOOD, 175 Strand, London, W.C.

seen on inspection of the numerous examples that were shown in woodwork, ironwork, piping, &c.

Bristol Pennant Stone Quarries Company, Limited.

The specimens of various works executed in the Pennant stone were seen to advantage at the stand of the above-mentioned company. The stone has peculiarities that distinguish it from other kinds of stone. It has a distinctive (blueish) colour. It is valued from the west to the east of England in many districts for use as paving and curbing. Notwithstanding its hardness, it is worked up to a most perfect surface where required for monumental purposes, and neither the plain surfaces nor the sculptured enrichments seem affected by any number of years, though subject to stress of weather. For steps, paving, &c., it seems as durable as any other stone.

The Cannon Holloware Company.

Those concerned in the manufacture of the variety of appliances that were shown at the stand of the company, have persevered in spite of difficulties till they succeeded in manufacturing what may be called a perfect ware in the special line they show, which consists in sanitary goods lined with a beautiful surface of porcelain on metal. It might be called an enamelled surface rightly, but that description would not do proper justice, as it is a genuine lining of porcelain on metal, with a perfect roll edge. The process could be seen as applied to nearly every kind of article, from baths and lavatories to small bowls. These goods are already much in request by those who know them. There is no chance of pinholes which lead to oxidation and destruction, and no expense in painting them is requisite. The company may be congratulated on the immense variety of articles shown, manufactured under this process. We understand the process, though not very long introduced, has found general favour.

G. Shrewsbury,

of Station Road, Camberwell, showed various gas-baths, patent "Calda" bath-heaters, patent gas conservatory boilers and portable oil hot-water apparatus. The instantaneous heaters will provide a warm bath in ten minutes. To meet the wishes of many customers, Mr. Shrewsbury produced a new pattern patent "Calda," with flue-pipe and fitted with plain gas-burners made to swing for convenience in lighting. The original "Caldas," however, fitted with atmospheric gas-burners, can be safely used without a flue, being perfectly free from smoke or smell. They are still being extensively sold and can with confidence

be recommended, thousands of them being in use without inconvenience or danger resulting. There was also shown a new improved registered asbestos gas-fire, in different sizes, at very reasonable prices.

F. Nutt,

architectural carver, modeller and designer, of Gough Street, Gray's Inn Road, W.C., showed specimens of his excellent work. We should mention that he is prepared to execute any style of work connected with wood-carving, having had about fifteen years in a joinery factory, where he had charge of the department of wood-carving, and was entrusted to carry out all the plans and designs of architects.

Thomas C. Fawcett,

of Leeds (E. Breething, manager, Dunton Green, Sevenoaks) showed Breething & Fawcett's patent sand-faced power brick machine. The machine will make 12,000 to 15,000 (by double delivery), or 6,000 to 8,000 (by single delivery), perfect sand-faced bricks per day, free from sand flaws or air bubbles; in fact a perfect solid brick, either best facings or common clamp stocks, and as the bricks are moulded much stiffer than by hand they are not put out of shape by wheeling to hacks or drying floor, and one-third the usual drying ground is saved. It will mould any clay that can be moulded by hand, either light loam or the strongest clay. It is fitted with patent automatic sander, and effects a great saving in sand and labour. No wires are used, and the power to drive is little more than to drive an ordinary pugmill. The pugmill can be made to work either horizontal or vertical.

The Paragon Bolt Syndicate, Limited.

This company had on view the excellent "Paragon" bolt, the convenience, merits and advantages of which are known to all who have employed it. It will not, however, be out of place to enumerate some of the advantages, for as compared with ordinary bolts it possesses much greater strength, cost for cost, and exceeding neatness, no beading to be cut away for socket. It shoots smoothly and requires no force, the dropping of door does not affect working of bolt. It has no springs, and is practically everlasting. The upper bolt on door can be fixed within easy reach, not of necessity at the top of door as with other bolts. The "Paragon" bolts are excellently made and finished, well suited for use on the highest class of work for doors, casements, cabinet work, &c. The flanges and tubes of the bolts are made to take the holes bored by the standard

"MANCHESTER" DYNAMO.

sizes of centrebits and twist drills, the larger one being bored first. We can hardly better praise the "Paragon" bolts than by saying we advise all to try them. The "Pulopn" catch is another of their patents, and though only just introduced has been greatly approved of already. The special advantages claimed for it are as follows:—Ease in fixing, practically no wood to be cut away, no projection on door, entirely automatic, closing of second door effectively locks the first, doors though firmly closed require simple but definite pull to open, reaching up to the top bolt entirely done away with, cheap and durable, saves time, temper and thumbnails. These catches are strongly made and well finished, and in their various forms can be used in any position on doors, either for keeping them closed or holding them open.

W. H. Harling.

The display at this stand was unique. The exhibitor, Mr. W. H. Harling, mathematical, drawing and surveying instrument maker, of 47 Finsbury Pavement, London, E.C., had certainly a very fine exhibit. All the requisites for architectural and surveying work were shown—levels of various kinds, levelling staves and ranging poles, land chains and tapes. Drawing instruments, of which Mr. Harling has been the manufacturer for nearly half a century, have, as a result of such long experience, reached a state of great perfection, combined with moderate prices. The clinograph, a very useful instrument for drawing angles of any degree, tee and set squares, water-colours, and a few optical instruments help to fill up an exceedingly attractive case.

The Pickering Block and Hoist Company,

23 Mount Pleasant, Clerkenwell, was for all engaged or connected with building operations a most interesting and thoroughly practical exhibit of the excellent appliances and specialties of their firm. Among these were shown several types of hoists, and the utility of these for service on works in progress was amply demonstrated. A variety of patent pulley blocks of all sizes and types were to be seen, also a variety of cranes, winches, gin-blocks, lifting-jacks, wheels, chains, &c. The appliances could be shown in action; visitors kept those in management of the stand well employed in that respect. Some of Pickering's hoists should be mentioned by name as particularly useful, viz. the "Universal" friction hoist and the "Quick Sack Hoist," fitted with new duplex brake; the "Climax" self-sustaining warehouse hoist, &c. These hoists are inexpensive to fix as well as inexpensive in price.

The Plastic Marble Co., Limited,

showed admirable examples of the work they have produced. Beautiful chimney-pieces, pilasters, &c., were exhibited, and could not be distinguished from actual marble-work. The plastic marble is an artificial—in other words, a manufactured—material, but, as before implied, scarcely distinguishable from real marble. It can be applied for all uses where marble is employed, and, beyond that, for purposes where marble could not be used. Many will value it also as ironwork of any kind can be encased by it. From wall decoration to decorative table-tops is no doubt a long step, nevertheless these and the intermediate requirements are satisfactorily met by the use of plastic marble. Any reproduction of the best marble-work is possible.

Wood & Ivory, Limited,

of the Albion Blue Brick and Tile Works, West Bromwich, had on view their Staffordshire blue bricks, &c. Specimens of the South Staffordshire marl from which they are made were also shown. The blue brickwork is of the most enduring nature, and while so extensively used in all parts of this country, the demand for it abroad and in the colonies is very great. The order for the whole of the blue bricks required by Messrs. Morrison & Mason, Limited, for the contract for the Birmingham Waterworks has been placed with this firm.

D. Anderson & Son, Limited,

of Belfast and London, displayed their silicate cotton, or slag wool, for soundproofing and fireproofing buildings. Anderson's patent hair fabric, as a non-conductor for covering pipes, of the best kind. It can be easily fixed, the difficulties attending its fixing, which involved time and trouble, having been successfully overcome, and any person can easily fix it or again detach it. Besides the silicate cotton, which is used for all purposes where a perfect non-conducting material is needed, in addition to felts of different sorts, viz. what are termed roofing felts, sarking felt, foundation felt, patent inodorous felt, &c., there was a large show of vulcanised indiarubber goods for all purposes.

Shepwood Fireproof Structures.

At stand 113, the "Shepwood" system for fire and heat-resisting and ventilating structures was shown, viz. combined fire and heat-resisting floors and finished ceilings, and combined brick or tile and concrete partitions. For the floors arched tiles moulded in porous terra-cotta, or other suitable material,

MUSIC.

NEW CO-OPERATIVE BRANCH STORES, PICTON STREET, LEEK.

ALMSHOUSES, FORD, BIDEFORD.

GREAT HALL AND STAIRCASE, GOSFORD HOUSE,
LONGNIDDRY, N.B.

are placed between rolled joists, spaced from 1 foot 6 inches to 3 feet or more apart, as required. The tiles are formed with skewbacks, and are so arranged that they can be placed in position after the rolled joists have been finally fixed. Concrete is run in between the skewbacks of the tiles and the rolled joists, encasing every part of the metal, including the under side of the lower flange, with a thick non-conducting layer, which is enclosed with terra-cotta or other suitable material. All main girders are completely encased in a similar manner. Concrete is filled in over the tiles in the usual way. The hollow spaces in the tiles run parallel with the joists, and ventilated air-spaces pass on either side of the joists for their whole length.

H. Hart,

of Commercial Road, E., had a large show of chimney-sweeping, drain-cleansing apparatus, &c., of which he is the manufacturer, being also an importer of malacca, rattan, bamboo and other canes. He has just completed the purchase of a large consignment of sweeps' long-jointed malaccas, and can offer a stouter and better quality cane than before at the same prices.

Thomas Potterton's

improved system of warming a house was found well worthy of attention by many persons. It is suitable for warming offices, hotels, restaurants, waiting-rooms, shops, warehouses, &c., or supplying hot water for dairies, manufacturing purposes, public baths, &c. Heat wasted from a kitchen fire is utilised, and Potterton's patent zigzag boiler can be fitted to any kitchen. The whole of a house can be warmed without having other fire in building except the kitchen fire, and no extra fuel for that is required. In cold weather a house can be kept warm all night. A special arrangement is provided by cistern, which will effectually prevent the pipes from freezing in cistern-room, and the radiators fixed about the house will have the same effect in other parts.

The Expanded Metal Company.

Conspicuously placed in the very centre of the Hall was the handsomely constructed pavilion of the Expanded Metal Company, in which the various qualities claimed by the company for their expanded metal lathing, &c., were effectually demonstrated. In it were to be seen *in situ* fireproof flooring, walls, cornice and column work, &c. It was surrounded by a balcony, also of expanded metal, the effect of which was excellent, and specimens of guards and fencing suitable for railways, farms, &c., were also shown. Since its original introduction to the building world as a lathing, this material has undergone many modifications and improvements, and now, in addition to its greatly increased value for building purposes, may be mentioned its suitability for fencing, gates, tree boxes, aviaries, lawn, horticultural and floricultural trellis-work, fowl runs, dog kennels, machinery, window and skylight guards, and for hundreds of purposes for which wire has heretofore been used. This company has purchased the patents and business of the British Metal Expansion Company, of West Hartlepool and London, and under the new process of manufacture can cut metal of any thickness up to a quarter of an inch.

The Andrews-Hawksley Patent Tread Company

showed in the Arcade their newly-introduced "Andrews patent reversible tread," which is made in three sections at prices ranging from 2s. to 2s. 9d. per foot super. The advantages claimed for this tread are safety, silence, strength, lightness and cheapness. In addition to ordinary stair treads, for which any of the sections may be employed according to the degree in which these qualities are required, this tread can be applied wherever a safe foothold is essential, such as for cellar flaps, covers for gas and water mains, hydrant covers, manhole covers for sewers, mats for public buildings, omnibuses, tramcars, railway carriages, passenger steamers, &c. The light section is specially suitable for small treads, such as tram and 'bus staircases, railway signal ladders, &c., where safety is essential and no great strength necessary. The tread being reversible is calculated to last four times as long as an ordinary tread. When the front blocks are worn (in about seven years), the tread can be turned round and the back blocks brought to the front. When these in turn are worn down (another seven years), the tread can be turned over and the other side worn in a similar manner, giving a total life of say thirty years.

&c., &c.

H. Hermann, Limited.

Owing to its conspicuous position and artistic appearance, Messrs. Hermann's exhibit attracted a large share of attention to the beauty of the carving produced by this firm, and to which we referred in our issue of the 22nd ult. The exhibit took the form of a pavilion, the interior of which was cosily arranged with a richly carved mantel and overmantel, an equally elaborately carved and ingeniously contrived bookcase and writing-table combined, framed *bassi-relievi*, &c., and on the outside were tastefully disposed carved panels, ranging from the simplest designs to the most ornate, and suitable to all purposes to which this form of decoration can possibly be applied.

C. G. Picking & Co.

This firm showed a practical application of their patent twin arch interlocking fireproof flooring, for which they claim the maximum of strength with the minimum of weight and thickness. These desiderata have been secured by adapting to hollow tubular blocks the twin-arch design, combined with the employment in their manufacture of a material that is both strong and refractory. The lateral interlocking arrangement is a most important feature in the design and the additional strength and security thereby attained needs no demonstration. The sections are in 2-feet working lengths and so made as to completely encase the under flange of the supporting girders. This floor does not need the extraneous aid of concrete to give it strength, and there is consequently no temptation to economise weight by the employment in the concrete of a combustible material like coke breeze, as is sometimes the case. The double-arched blocks possess in themselves the requisite strength, and without the addition of concrete will carry a safe load of 5 cwt. per square foot. They need only the covering of fire-resisting grout, supplied with them, to form a homogeneous floor. The finished face may be of wood, tiles, stone, or cement. Such a floor does not exceed 6 inches in depth and the value of the saving in head room on each floor throughout a high building will be at once appreciated by all conversant with building construction. On the other hand, if for any special reason a heavier and thicker floor is required, there is no obstacle to such being constructed. The soffits of the tiles are provided with dovetailed ribs that give a substantial key for plastering. Plaster so fixed has remained intact under severe fire test. The same principle is adapted to walls, partitions, &c. Messrs. Picking & Co. are also showing their new patent conduit for electric light mains,

telephone and telegraph wires, &c, which has been designed to provide a simple, efficient and permanent underground casing for insulated cables, &c. It is made in hard burnt earthenware, and each length is coated internally and externally with bituminous matter (of which all joints are also made), which thoroughly combines with the earthenware, giving it a glass-like surface which will not peel off and cannot be removed. Among the advantages claimed for this conduit are its great strength, which will withstand a high crushing strain; that it is a non-conductor of electricity, is gas and water-tight, and thoroughly proof against any chemical action that may be set up by acids or gases found in the ground in which it is laid. The material of which the conduit is composed is not affected by any change of temperature; it neither expands nor contracts, joints therefore cannot be strained or broken. A most important point in connection with this system is that no condensation arises, as in stoneware or iron, and short circuiting from this or any other cause cannot occur. It is supplied in lengths of 3 feet of various sections and sizes, as may be required, and carrying from one to seven or any other number of cables. Each duct is intended to carry one cable or ribbon, and the internal edges of all the joints are well rounded, to prevent the main from chafing when being drawn in or out.

G. J. Farrow.

Conspicuously towering above all the other exhibits Mr. Farrow's improved portable iron scaffold attracted attention. The advantages claimed for these scaffolds are speed in erection, adaptability to the height of any room or building, movability in any direction upon castor-wheels, the tyres of which are of indiarubber, and they are carted, erected, taken down and removed without any trouble to the hirer. It is a portable fabric formed of iron tubes which fit into each other like the portions of an iron bedstead. The patentee informs us that a scaffold of this kind may be set up at about one-fourth of the cost of the old-fashioned sort, and as it may be built of any height up to 100 feet, it is admirably adapted for the cleaning or repairing of lofty roofs and ceilings, and especially so in cases where the cost and cumbrousness of the old system would be prohibitive or nearly so.

W. Parham.

Mr. Parham claims that his are the "best cheap green-houses ever offered," and judging by his exhibit, he is no doubt in a position to substantiate this not too modest claim,

C. J. EKMAN & CO.,

24-25 FENCHURCH STREET,

LONDON, E.C.

for the houses shown were well designed and finished, and can be put up at a wonderfully small cost, the cheapest somewhere about fifty shillings. They are made of well-seasoned red deal, and include matchboard base, sash-door with rim lock and brass furniture, ventilating sashes with iron openers painted one coat in oil, 16-oz glass and materials for stages on each side. They are made up in sections, the ends and sides being complete, and only requiring to be screwed together at corners and the rafters laid on. Any handy-man can put one together in three or four hours.

W. A. Smith,

of Northampton, in his display of machinery and mechanical apparatus, showed a cross-cut pendulum saw, to take 24-inch saw; a planing machine, with rising and falling bed; set crushing rolls in frame, 3 feet long by 18 inches diameter; an iron circular saw-bench, to take 36-inch saw, fitted with one new 30-inch saw, fast and loose pulleys, and throwing-out gear; wrought-iron brick trucks; and an assortment of accessories for brickyards, &c.

Henry Bassant

had an unusually fine display of his parquet flooring. For a perfect floor combined with pleasing effects gained by arrangement of different woods, nothing better could be seen. The teak wood parquet flooring speaks for itself and needs no further recommendation.

E. S. Hindley,

of Bourton, Dorset, showed his steam-engines, horizontal and vertical, hoisting and winding engines, semi-portable and winding engines, high-speed engines, and also vertical boilers, Cornish boilers, multitubular boilers, colonial boilers, &c. Also the "Bourton" donkey feed pump and sawing machinery, circular saw bench and circular band saw machines.

Stourbridge Brick Company.

This company had a large display of their manufactures in fire-brick goods, and this line of work was admirably shown by them, nearly every variety for all purposes and all sizes being seen. Sanitary goods were also well represented, and among them excellent closets and appliances in connection. A small model railway truck was seen, loaded with the fire-clay from which the fire-clay goods are made. As a display of fire-brick wares, such a display could seldom be seen at any exhibition.

W. Osment & Co.,

of Clapton, had a particularly good exhibit of his productions in joinery and turnery. The improved machinery for producing the work patented by the firm is evidently successful, the work being so perfectly executed in the shortest possible time. It also spoke well for the articles displayed that little or no time has been given to "finishing them up," as is so often required to be added to machine-worked goods. Samples were shown in great variety—balusters, railing, newels, &c., most elegant specimens of woodwork, and to which we strongly invite the attention of architects, builders, &c., and the general public. Many new and excellent designs were shown as lately executed. The firm's registered system of subdivided panels worked from the solid wood, and so much superior to the usual run of this kind of work, was well shown. Messrs. Osment & Co.'s exhibit was one of the best we have seen for a long time.

Hall, Beddall & Co.

had a first-class exhibit from the point of view of a sanitarian, as they showed their patent sanitary dust-trap, which is adapted for fixing in either brick or iron shafts, where several floors or flats have access by means of openings for the purpose of emptying dust or refuse into a shoot. The defects, not only disagreeable, but also injurious to health, of the ordinary hopper arrangement are by this time well known, and these defects have been eliminated by the patent sanitary dust-trap of Messrs. Hall, Beddall & Co. However carelessly handled it cannot be opened to the shoot and the house at the same time, and the working is very simple. The system has already been largely adopted.

Samuel, Sons & Benjamin,

of Fenchurch Street, E.C., showed Gurney's low-pressure hot-water heaters and radiators. This system has been extensively used in Canada and the United States for over half a century, and having had many orders and inquiries from home, the Gurney Foundry Company, Limited, have established a depot in London. Canada has one advantage over home—that it is always well prepared to meet cold weather. Among the appliances are the Oxford hot-water heater, said to be the quickest in circulation of any low-pressure known—an assertion we are not inclined to controvert after seeing it in action. The Oxford double-crown hot-water heater, the Oxford quilted radiators, and other hot-water and steam radiators. Messrs. Palowkar & Sons have recently taken many important contracts in London.

MAURICES

MAURICE'S PORCELEINE,

For Painting and Preserving Wood, Stone, Metal, Plaster, or any Surface on which Paint can be applied.

BRIGHTER THAN ENAMEL.

EASY TO APPLY.

NO BRUSH MARKS.

Cheaper than Paint and Varnish where a glazed finish is required. A Saving in Labour, only two or three coats being required on new work.

SAMPLES FREE TO ARCHITECTS AND BUILDERS.

FOR WALLS AND WOODWORK.—Maurice's Porcelaine is the best article in the market when a bright and durable finish is required; it is easy to work and gives a lasting glaze equal to China.

CEILINGS.—Our White is incomparable, and will keep its colour for years; it has binding qualities that prevent Ceilings from Cracking.

ENGINEERING.—For Iron or Metal-work of all descriptions it is a protective against Corrosion, and gives a beautiful finish, and on account of its heat-resisting qualities is in every way suitable for Stoves, Engines, Electrical Apparatus, &c.

All the above remarks are Guaranteed, being the results of Practical Tests.

MAURICE'S LIQUID GOLD.—This is valuable for Interior Gilding, being an Improvement on Ordinary Gold Metallic Bronze Paints. Price, ready for use, 5s. per lb.

Chief Office and Works:—GAINSBOROUGH ROAD, VICTORIA PARK, LONDON, N.E.

Yates, Haywood & Co.

Among the varied goods that comprised the exhibit of Messrs. Yates, Haywood & Co. were specially to be noted their new patent "Quadrant" kitchener, an article of substantial construction, made with exquisite finish, and having for its special feature a self-adjusting lifting-fire, which can be raised or lowered to any point with one hand. The movable parts do not come in contact with the fire, consequently there is no wedging or getting out of order. The range fire cheeks and back boiler can be taken out without disturbing any other part of the kitchener. This kitchener is made with over and under draught ovens, and can be made with enclosed iron flues, requiring no brickwork setting. They had also from their large warehouses and showrooms, 95 Upper Thames Street, samples of very highly finished baths, with rolled edges and mahogany capping; also a very considerable selection of wood mantels and over-mantels in oak, mahogany, and white wood, of artistic design and exquisite workmanship, filled with ornamental tile stoves with electro-bronze decorations; tile hearths, fenders, and fire brasses. A selection of very handsomely carved marble chimneys in Carrara marble have attracted a great deal of attention, the designs being Louis XIV. and of the Adam type. These, together with this firm's specialty in marble chimneys, viz. their Lavande Ecossais and gris rouge samples, comprise groups of marbles at once handsome in design and beautiful in colour. A specialty in cooking ranges—to supply a demand much increasing by the erection of artisans' dwellings in the Metropolis—is Yates, Haywood & Co.'s "Guinness" patented self-setter range. The oven of this range can be easily removed at will, exposing the whole internal construction of the range to view, and making it very easy to clean the flues, however much neglected, and to repair any part without taking the kitchener out of position.

Joseph Williamson & Co.,

Midland Foundry, Wellingborough, Stand 186, exhibited their "improved Graphic" self-setting, open and close, and lifting fire ranges, a 6-foot size of which is shown in action. This firm's ranges combine all the latest improvements of this "up-to-date" age. The lifting fire can be regulated to a depth of from 12 to 6 inches in one movement, and has the advantage of possessing vertical bars, not shaped, and has no slots or ratchets at sides or centres to get out of order, or to obstruct roasting in front. The lifting portion of these ranges consists of a

"cam," which is fixed in position under the bottom grate, and away from the action of the fire. A novel feature of these ranges is the patent rising table to the fire, which rises and falls, being always on the same level as the fire, and which can be detached instantly. This firm claims that this is the only range made with this useful table. These ranges require no brick flues, being self-setting, having enclosed cast-iron flues. The hot plate is extra deep and of thick metal. The ovens (the fronts of which are particularly bold and striking) are very large, and run back the entire depth of the hot plate—special provision has been made for their efficient ventilation by a simple arrangement of dampers. These ovens can be heated top and bottom at the same temperature by their special under draught, the flames from the fire passing completely round the oven. By the arrangement of the ashpans hopper the fire is convertible at will into slow or semi-slow combustion, thus effecting an enormous economy in the consumption of fuel. We understand that these ranges are made all sizes, and, although those shown have handsome tile coves and tile jamb mouldings, the prices can be considerably reduced by having iron coves. To architects and others who require a good-looking, well-finished, self-setting range, we would recommend them to apply to Messrs. Williamson & Co. for lists and prices. We understand that Mr. J. Yeomans, of Roehampton Lane, S.W., who is the London and country representative of this firm, and who has had many years of practical experience in the trade, has designed these "improved Graphic" ranges.

Ellis, Partridge & Co.

At Stand No. 7, Messrs. Ellis, Partridge & Co. (of Leicester and London) exhibited red-facing bricks and ornamental brickwork from their Redbank Works, Measham, and also their Woodville Works, Burton-on-Trent. Their exhibit surpassed their previous efforts in the excellence of the quality of the bricks, &c., shown, and in the great variety of designs, which numbered several hundred. During the past year the firm have put down new and improved machinery by which the manufacture has been brought as near perfection as possible, and the output considerably increased. No effort is spared to keep pace with the times. The Redbank works are now lighted by electricity. The firm claim, and apparently with good reason, that their moulded and ornamental bricks are unsurpassed for finish and clear, true lines, a point most essential where first-rate work is required. "Redbank" bricks are

SUPERFINE FLAX LINE.

The above article is now being manufactured and sold in large quantities for Greenhouse Sashes, Public-house Shutters, and other heavy work. The Manufacturers would recommend it for its strength, and the large amount of wear in it, consequent on its peculiar manufacture.

AUSTIN'S IMPERIAL PATENT FLAX SASH AND BLIND LINES (two Prize Medals awarded). The Manufacturers of the above articles particularly wish to draw the attention of the trade to their Imperial Patent Flax Sash Lines, of which they are now making six qualities, all of which they can strongly recommend, as they have given unqualified satisfaction to the trade for now over One Hundred Years, and the Proprietors continue to give their personal attention to the manufacture of these goods.

They also invite the particular attention of the trade to their IMPERIAL PATENT BLIND LINES, which are very superior to anything yet offered.

They can be obtained of all Ropemakers, Ironmongers, Merchants, Factors and Wholesale Houses in town and country.

N.B.—Please note that all our goods, as advertised above, are labelled either inside or outside with our Trade Mark—The Anchor.

WOOLPITS, SURREY. FOR SIR HENRY DOULTON.

BY ERNEST GEORGE AND PETO.

PROOFS of this Illustration, which appeared in "The Architect" on June 6, 1885 (now out of print), can be obtained on application to the Publisher, price Sixpence each, post free; on roller, Ninepence.

thoroughly weather-resisting, and now widely used for public buildings not only in London, the Home Counties, and throughout the Midlands, but are even sent as far north as Yorkshire and Northumberland. The "Woodville" sand stocks are also very popular for the building of churches, country mansions and suburban villas, &c., being rich in colour and very similar to Fareham and other south country makes.

The Copal Varnish Company.

The well arranged stand of this company showed off to advantage the various excellent qualities of the paints, enamels and varnishes manufactured by them. Conspicuous among these were Randall's Paris White Japan, a pure white decoration for bath and bedrooms, hospital wards, &c. It is inexpensive, and can be supplied in any tint of colour. It has a magnificent gloss, but can be flatted if preferred. Randall's Paris White Japan evidently keeps its colour and brilliance very well, as a panel was exhibited which was prepared for the Kimberley exhibition, 1892 (where it obtained a gold medal); this is still in excellent condition. Randall's Adamantine Enamel, a most effective preventative against damp walls, is also very useful for putting on plastered walls and ceilings before painting or distempering. A large collection of varnished wood panels showed the fine brilliance and body of the varnishes made by this firm, and their excellent flowing capacity was also advantageously demonstrated. The special advantages possessed by the Copal Varnish Company's varnishes are their great brilliancy, durability and freedom from bloom.

M. Tibbitts,

of New Southgate, North London, is the inventor and patentee of the slow-combustion plate, or improved air-supply regulator for stoves, which can be applied to any register or other open stove and open kitchen ranges for economising fuel and obtaining more heat. Though only introduced during the last twelve months, it has given the greatest possible satisfaction to all who have tried it. It is applicable both to the ordinary register or open stove in sitting-rooms, for the purpose of saving the consumption of fuel and obtaining more heat, also to open kitchen ranges, for saving fuel, obtaining more heat for roasting, &c. It consists of an iron plate, the size of the bottom of the stove or range, with two doors running in slides and opened and shut by levers. The plate is fixed on the bottom of the stove or range right underneath by the aid of two small screws and nuts, which hold it up to the bottom. When the doors are

open (for lighting the fire or drawing it up) the levers or handles very slightly project out in front. When the doors are closed (to obtain slow combustion and draw out the heat) the levers or handles will be as far from one another as possible and hidden under the bottom bar of the grate.

Baird, Thompson & Co.

made an excellent display of their ventilating appliances, which we have so often drawn our readers' attention to. Also there was noticed their drain-test machine, than which nothing could be more perfect. The merits of the new turret ventilators were well shown by models. The exhibit did justice to Messrs. Baird, Thompson & Co., being a very good indication of their success as ventilating, heating, sanitary and consulting engineers.

Albion Clay Company, Limited,

gave a very interesting display of their goods. Several new departures have been made by this company in the way of excellent and improved sanitary appliances. We can only describe one at present, and it is their patent channel bend for manholes and inspection chambers. These bends have been designed to prevent the splashing which now takes place in the chambers. The improvement consists in arching over the lower or outlet end of the bend. A lip or bend is also formed in the upper wall of the channel bend, whereby the sewage in striking the same is deposited directly into the main channel instead of bending opposite. Another improvement consists of leaving on the socket end a portion of the pipe cut so as to be parallel with the brickwork, which the bend at present in use does not possess, and cutting away the brickwork is necessitated. A description of other novelties shown by this firm must for the present be deferred.

Callender's Bitumen Telegraph and Waterproof Company, Limited,

provided a show of their specialties, from the point of view of architects, contractors, &c., very useful. Also were shown their manufactures connected with insulation of electric wires, cables, &c. What they term the "pure bitumen damp course" is to be recommended, as it will stand results in use. We would describe it as a combination of canvas and of pure bitumen as obtained from the asphaltum lake in Trinidad. No damp course, to our knowledge, has proved altogether lasting if of hard and fast material. The best of constructed buildings after erection settle, and in that settlement, however small it

THE WELL-KNOWN FRIEZE, ENTITLED

"THE CORN FIELD."

Length, Fourteen Feet Seven Inches by Fifteen Inches deep.

A SPLENDID EXAMPLE OF COLOUR-WORK IN PERMANENT INK PHOTO, BY
M. PAUL ALBERT BAUDOIN.

This magnificent Illustration was presented to the Subscribers to "The Architect" in 1886. A few Proofs were taken, which immediately became out of print.

OPINIONS OF THE PRESS.

"We are not surprised to hear that there has been a great demand for the beautiful reproductions of the well-known frieze by M. Paul Albert Baudoin, entitled 'The Corn Field.' The plates have been reproduced by subscription at half a guinea the set, and so great has been their success that a second edition is being issued."—THE LADY'S PICTORIAL.

"They are beautifully done in colours by the permanent ink photo process, and form a very artistic and pleasing set at the extremely moderate price of half a guinea."—THE STAGE.

"The well-known frieze entitled 'The Corn Field,' which is a splendid example of colour-work in permanent ink photo, by M. Paul Albert Baudoin, is to be reproduced by subscription of half a guinea a set. They are exceedingly artistic, and would grace the walls of any house."—THE GENTLEWOMAN.

AND NUMEROUS OTHERS.

In consequence of the almost daily demand for these Plates, they have been reproduced by Subscription at Half a Guinea the Set, and are now ready for issuing.

P. A. GILBERT WOOD, 175 STRAND, W.C.

May be had framed in Solid Oak Frames with Mounts, at Three Guineas the set of Five Plates.

may be, it disturbs any kind of damp courses that are rigid or even slightly rigid. Some play must be allowed while calculating that buildings are liable to settle. This difficulty is apparently exactly met by what we have termed a combination damp course of bitumen and canvas. The tests of experts corroborate our remarks.

R. Morris & Son.

Messrs. Morris & Son are to be congratulated on their fine show in glass work and decorations on glass. Their ability in design and execution were well shown. The display was what most will term a magnificent one, though many are well acquainted with the lovely effects that can be produced on glass. In addition to excellent fascia work and lettering, the samples of ornamental work represented landscape views, &c, floral work, bird and insect life, &c, of the most pleasing description.

H. F. Buchan & Co.

showed their improved sink and lavatories, traps, thimbles, &c., as approved and adopted by the County Council. One feature was their soil-pipe junction, with patent disconnecting metallic joint to fit any closet outlet. The exhibit was an interesting one, and we trust it received the attention it deserved.

Gray's Chalk Quarries Co., Limited.

The non-porous bricks were shown at the stand of this firm. Dwarf structures also exemplified the use of brickwork in practice. One claim is that this company are the only manufacturers of non-porous brickwork. A window opening had also been constructed to give visitors an opportunity of judging of its decorated effect, aided by combination of colour in brickwork.

T. Freeman

Mr. T. Freeman, of Phoenix Street, St. Pancras, exhibited at his Stand (No. 117A) a very choice collection of art tiles, glazed and vitreous, the product of works in which he is interested in the potteries.

At the same stand J. Fielding, of Beggar's Well Quarries, Alton (London offices and stores, 200 and 202 Phoenix Street, St. Pancras), showed samples of red sandstone in various forms. These quarries have the credit of producing some of the largest blocks obtainable in the kingdom, without faults or anything detrimental to durability or appearance. As an indication of the excellence of the stone, it has recently been

selected by Messrs. Giles, Gough & Trollope, of Craven Street, for the extensive asylum in process of erection at Cheddleton (about 50,000 cubic feet of the stone being prepared for the building). We are informed the following architects have adopted this stone in several churches and public buildings, viz.:—Sir Arthur Blomfield & Sons, the late Ewan Christian, and the late A. W. Pugin.

Also the Midland Glazed Brick Co., Limited (London offices and stores, 200 and 202 Phoenix Street, St. Pancras), exhibited a well-selected assortment of white and coloured glazed bricks. They appear to maintain the reputation of this company, who claim from the hardness of their glaze and strength of their clay an absolute immunity from the scaling and crazing which is too often seen in other bricks.

Morgan & Co.

Messrs. Morgan & Co. showed working models of Nowell's patent reversible sliding sash-window, and patent reversible French casement. Simplicity is the strong feature in these sashes, and the reversible fittings, which are durable and inexpensive, can be easily applied to all existing windows, and their adoption enables all cleaning, painting and glazing operations to be carried on from the inside of the room, thereby obviating the risk of accident.

James B. Petter

had a handsome display of various patterns of his patent Nautilus grate, which is a fire-brick lined, slow-combustion, smoke-consuming portable dog stove, in form resembling a nautilus shell or volute, and is an artistic, scientific, economical, cleanly and powerful fireplace. A delightful warmth is radiated directly from a bright and glowing open fire, and indirectly from its outer case, an equal temperature being maintained throughout the apartment. A register door, for sweeping, encloses the chimney immediately over the grate, thus obviating any waste of heat, and provision is made for regulating the draught to the greatest nicety, whereby the fuel consumption is claimed to be marvellously small. Another variety is the patent "Mail-Clad" stove, which has enormous heating capacity. The patent "Mermaid" boiler is also shown. This is so constructed that any incrustation arising within it falls to the bottom, away from the action of the fire. Its large capacity renders a hot-water cistern unnecessary in moderate sized households. The "Yeovil-Leamington" kitchen range with "Mermaid" boiler complete is also shown.

Mr. Petter attaches great importance to his Sou'-Wester roof-plate, which is adjustable to all roofs, ship decks, &c., and consists of two castings, a plate having a dome on its upper service with a hole through same, and a nozzle with a flange around its bottom edge fitting on the dome and forming a ball-joint adjustable to any pitch of roof, ship's deck, &c. The plate is fastened to the rafter in the usual way and the nozzle then placed on the dome, being secured with the bolts through the holes arranged to take them. The lower or taper part of the nozzle receives the pipe from within the building, and the top or spigot end carries that used above the roof.

Martin, Earle & Co.

This firm, whose well-known cement factory at Rochester has recently undergone extensive alterations, while their plant has at the same time been greatly increased and improved, are now in a position to double their late output of Portland cement, tested briquettes of which they had on show. This cement, which has a high reputation for high burning and fine grinding, contains no Kentish ragstone, and is in fact guaranteed absolutely free from adulteration of any kind. Messrs. Martin, Earle & Co. have received from Messrs. Stanger & Blount a report on the strain-resisting qualities of their cement, with which they are justly so satisfied that they have had it reproduced in facsimile and will be glad to send a copy of it to anyone interested in such matters.

Linoleum Tile Company.

This company, whose exhibit occupied the same position as last year, displayed a varied collection of patterns, among which were several new ones. Among these were a rich design in Oriental style, of which the colouring is particularly good. Our readers are for the most part familiar with the advantages possessed by this system of solid inlaid floor covering; but for the information of those who are not, we may mention the following:—They are noiseless and pleasant to walk on, waterproof and warm to the feet, not slippery, and will neither buckle nor blister. The colours and pattern retain their brightness after years of wear, as they are solid, go right through to the backing, and consequently do not fade until the material itself is actually worn away. Any pattern can be renewed at a few days' notice, whereas the ordinary designs in linoleum, &c., can seldom be matched after once being laid down. When any special part becomes worn, or accidentally damaged,

it can immediately be replaced without disturbing the remainder of the floor-covering, thus effecting a great saving in renewals. The unavoidable waste of material which occurs in fitting awkward corners and other recesses, with coverings made from the piece, is entirely obviated by this system, as the linoleum tile is cut in sections varying in size. The tiles can be laid on wood, stone, or cement, and have the same artistic appearance as encaustic tiles, without being so expensive. Any variety of colours can be had in heraldic, æsthetic, grotesque, or other designs, and any pattern, crest, or monogram, can be made and delivered within a few days from date of order. The effect of these tiles is greatly enhanced if they are polished with beeswax after cleaning.

Edward Harris

showed three working model sash frames with reversible sashes, of admirable simplicity, arranged so that the glass on the outside can be cleaned inside of a room, and thus avoid the danger of ladders and sitting on sills of windows for the purpose. They are efficacious and inexpensive.

A novelty was shown by the Imperial Manufacturing Company in the way of a fire-lighter. Architects and builders have to furnish houses for the public to live in. Among other necessary fittings of the dwelling, fireplaces are provided, and this company has come to aid the public by helping them to more easily use what the builder has fixed in regard of fireplaces, &c. The fire-lighter has been tried by a number of persons during the past week; the cost is practically nil, and it has been so much appreciated that we are pleased to call our readers' attention to it.

The following are the results of the handicrafts competitions on March 30, the judges being Professor Banister Fletcher, Messrs. A. Baker, H. Dawson, B. F. Dicksee, F. Farrow, W. Grellie, F. Hooper, H. Leonard, J. S. Quilter, H. D. Searleswood, W. C. Street, and the hon. secs. H. Phillips Fletcher and T. Locke Worthington. *Bricklayer*: Bronze medals to T. H. Smith and John Burgoyne; certificate of merit to Frank Mills. *Carpenter*: Silver medal to W. Wyatt; bronze medal to A. S. Sewell; certificate of merit to S. Evans. *Joiner*: The work not considered of sufficient merit to award medals or prizes. *Mason*: Bronze medals to Francis Montague and Albert Sugg; certificate of merit to John Hawley. *Modelling in Clay*: Silver medal to C. Giddings; bronze medals to A. H. Borrondale; bronze medals to Robert Bussey and P. J. M. White. *Painter and Decorator*: Bronze medal to S. Moore. *Plasterer*:

(To be concluded.)

In conclusion we may say that the exhibition, which was closed yesterday by their Royal Highnesses the Duke and Duchess of Fife, has been a pronounced success, and the able managing director, Mr. Montgomery, and the Council of Architects are to be congratulated on the perfect way in which the work of the exhibition has been carried out. During the last week the musical arrangements have been under the supervision of Mr. Glenn Wesley, and have been a great success.

TRADE NOTES.

In the construction of the Friargate Board Schools, Scarborough, Mr. J. C. Petch, architect, great attention is given to the ventilation, for which the "Climax" latest improved invisible roof ventilators, supplied by Messrs. Cousland & Mackay, ventilating engineers, Glasgow, are being used.

A NEW turret clock at the Chorlton-cum-Hardy Conservative Club, Manchester, erected by public subscription by all shades of politics and denominations, was set going at four o'clock on Saturday last, the 30th inst, by Mr. Bingham, chairman of the Local Board. The clock shows the time upon three external illuminated dials, and strikes the hours upon a bell placed in the turret. The work has been executed by Messrs. W. Potts & Son, clock manufacturers, of Leeds and Newcastle-on-Tyne.

MR. J. ARNOLD, of St. Paul's Road, Camden Town, N.W., has recently shown us samples of a very fine clean sand which he is supplying for the North-Eastern Hospital, Homerton. Samples of this sand have been recently exhibited by him at the Building Trades Exhibition at the Agricultural Hall, and were very favourably spoken of by architects and builders.

THE Wimbledon Cemetery Chapels, Wimbledon, are being warmed and ventilated by means of Shorland's patent Manchester stoves, with descending smoke flues, the same being supplied by Messrs. E. H. Shorland & Brother, of Manchester.

VARIETIES.

AN excellent likeness of Mr. G. H. Rayner, F.S.P.A., the writer of our weekly article on patents, appears in the current number of *St. Paul's*.

WE have pleasure in directing our readers to the top advertisement upon page xiii. of this issue, referring to the newly-established "Exchange." It appears from a perusal of the prospectus to be an excellent institution, and from the very reasonable offer the proprietors make as a test to the utility of such an Exchange, we think it is worthy of careful attention.

MR. JNO. WOOLLEY, the railway contractor, died somewhat suddenly at his residence in Wrexham on Sunday. Among the railways in North Wales that he constructed were the extensions of the Wrexham, Mold and Connah's Quay line to the Hawarden Bridge over the Dee, and from the Exchange Station into the centre of Wrexham.

MR. JAMES WILKINS, the Bristol builder, died at Clifton on March 28. He erected the Children's Hospital, the Bristol Grammar School, St. Nathaniel's Church, and the additions to Christ Church, Clifton, and removed St. Werburgh's Church from the city and re-erected it on its present site near Mina Road. Mr. Wilkins was in his sixtieth year.

THE Rev. H. E. Hulton has offered 1,000*l.* towards the cost of restoring the ancient church of Little Leighs, Essex.

BUILDING AND BUILDERS.

THE Wesleyan Chapel, St. John's Square, Clerkenwell, is to be enlarged. At the meeting to make arrangements a sum of 3,500*l.* was promised.

A SCHOOL for the deaf and dumb and blind children of North Staffordshire is to be erected at the Mount, Penkull, from plans by Messrs. Scrivener & Sons.

THE Herts County Council have adopted the following resolution:—"That having regard to the requirements of the Government architect and to the economy that will result in the future working of the asylum, as well as in the proportionate cost of construction, it be a recommendation to the County Council that the asylum should, in the first instance, be constructed for the reception of 560 patients instead of 400, at an estimated additional cost of 15,000*l.*"

"OPTIMUS" IMPROVED PHOTOGRAPHIC OUTFITS. EXTRA LONG FOCUS.

British Journal of Photography says:—"The present model Rayment Camera is among the very lightest of actually rigid cameras offered to the public. The rapidity of opening and closing is greatly facilitated by the additional arrangement for throwing the pinion out of gear from the rack. There is no curtailment of view when lenses of short focus and wide angular aperture are in use. All movements necessary to the modern scientific photographer are included in this compact instrument."

Including Rayment Camera, Three Double Dark Slides, "Optimus" Rapid Rectilinear Lens, Instantaneous Shutter, Tripod Stand, Waterproof Case, complete—

$4\frac{1}{2} \times 3\frac{1}{2}$	5×4	$6\frac{1}{2} \times 4\frac{1}{2}$	$8\frac{1}{2} \times 6\frac{1}{2}$	10×8	12×10	15×12 inches.

THE Boston School Board have secured sites for two schools, which are to be erected without delay.

AN inquiry has been held before Mr. Codrington, C.E., Local Government Board Inspector, in consequence of an application of the Cheshire County Council to borrow 80,000*l.* for the purpose of enlarging the Upton Asylum. Mr. J. L. Grayson, architect, Liverpool, and Mr. Stanhope Bull, the county surveyor, explained the plans. There was no opposition.

AN insanitary area of 77 acres, in Leeds, having 3,684 houses and shops, most of which will be taken down, is to be remodelled by the Corporation at an outlay for clearances of between 300,000*l.* and 400,000*l.*

TRADE AND SOCIALISM.

ON Friday, March 29, Mr. John Harrison delivered an address in the Merchants' Hall, Edinburgh, to the members of the Edinburgh Chamber of Commerce and the Edinburgh Merchant Company, on "The dangers to the trade of this country from the spread of Socialism." He began by explaining that, speaking as he did to business men, he would confine himself to the position of antagonism which Socialism took up to business in its widest sense. To both the manufacturer and the merchant Socialism did not say, "You must conduct your business honourably and liberally." What it did say to them was that the day of the manufacturer and the merchant was past, that they must be wiped out and that henceforth the State must be the sole manufacturer and trader. These being the aims of Socialism, it naturally followed that it was forced to attempt to carry out its principles by acquiring political power, and so affecting legislation and changing the whole relations of Government to trade. Socialism, or as it was called to-day, Collectivism, aimed at revolution, not reform. It sought to put an end to individual freedom and individual action. In the words of Mr. Bradlaugh, "It denied private property and affirmed that society, organised as the State, should own all wealth, direct all labour and compel the equal distribution of all produce." Property was theft, and capitalists were thieves, and the State when it took possession of all capital would be carrying out only a great act of justice. They would see that this theory appealed only to the labourer who worked with his hands. It gloried him as the only real worker. It denied all moral worthiness to thrift or to him that created

capital by saving, and necessarily justified the man who consumed all he made. It was easy to show the nonsense of this doctrine, but it was dangerous nonsense if preached, as it regularly was, to masses like those of the East End of London, who had no capital and no likelihood of ever being in a position to acquire it. They had a monthly periodical published in Fountain Bridge, Edinburgh, which stated in its opening number that it "will advocate the public ownership and management of the land, the mines and all the means of production and distribution, such as railways, shipping, factories, workshops, &c.," and the means to attain this result would be by the working classes using their political power. That was an example of Socialist literature, and if they replied that it was stupid stuff, written by irresponsible scribblers, he asked their attention to the proceedings of the last trades congress at Norwich, which professed to speak for more than 1,100,000 of the working men of the country, and the President of which maintained that the only direction in which they could look for the solution of their industrial problems was that of Collectivism. The congress, as a whole, had certainly walked up to the precept of its President, and had reached its "grand climacteric" when it carried a resolution in favour of nationalising "the whole of the means of production, distribution and exchange." He asked them to look with him at this Collectivism, and understand the leading idea on which it was developing its attack on the present order of society. At present we acted on the doctrine of *laissez faire*, the doctrine, namely, that "every man, so long as he does not violate the laws of justice, is left perfectly free to pursue his own interests in his own way, and to bring both his industry and his capital into competition with any other man or order of men." It was a doctrine the application of which had resulted in a marvellous development of commerce, science and civilisation. It was a rule of the survival of the fittest which had led to the development of strong individual character. We bowed before the strife and competition arising out of individual action because we believed it to be the law of life, and the only way in which the world was kept from sinking back into barbarism. But Collectivism intended to put a stop to all individual action, and to this end compulsion was to be used, for the Collectivists were not such fools as to believe that the world as at present constituted could be altered by natural means. And so the disciples of Collectivism were to act as one man in attempting to seize the Government, and thus enforce their new system by Act of Parliament. The Collectivist could not find an

WORKS, ROTHERHAM. Estab. 1854.

English word to express his desires and so he borrowed a French one, and talked of the *solidarité* of the working classes, the plain English of which was that the working man was to give up all his individuality for the good of his class. And this *solidarité* once secured was to be kept up by legal compulsion, just as the discipline of the trade union was kept up by class compulsion—moral suasion enforced by bludgeons. Was not, he asked, the great Scottish coal strike an example of this kind of *solidarité*, which nothing but fear of violence kept up so long even as it lasted. Let them also consider the programme of the church militant of Collectivism—the Independent Labour Party—as laid down by Mr. Keir Hardie in the January number of the *Nineteenth Century*; and let them mark how individual action was to be abolished by law and the State was to supervise life and control it. There were seven items in the programme:—(1) Restriction by law of the working day to eight hours; (2) abolition of overtime, piecework and prohibition of child labour; (3) provision for the sick, disabled, aged, widows and orphans, the funds to be obtained by a tax upon unearned incomes; (4) free, unsectarian, primary, secondary and University education; (5) taxation to extinction of unearned incomes; (6) the substitution of arbitration for war and the consequent disarmament of nations. The believers in Collectivism were not, indeed, sufficiently numerous to put their principles into force, but ideas born of Collectivism were working like leaven, disturbing the relations between employers and employed, to the detriment of both; they were affecting legislation, and threatening to affect it even more in the future. Collectivism was straining the relation between the capitalist and his workmen by preaching the doctrine that capital was theft; and during times of strike the workmen were apt to forget prudence and common sense under the fatal counsels of the Socialist agitator. But the ideas born of Collectivism were already most seriously affecting business by the way in which they were influencing legislation, and through the fear which filled men's minds regarding the legislation of the future. Collectivism hoped for the time when the State would interfere in every relation of life. In this country, Socialists were steadily working to gain two ends through legislation—first, to give *solidarité*, as it was styled, to the working classes by legislative enactments regarding hours of labour; and, secondly, to throw on the State a host of duties now performed by men individually or through voluntary association. With regard to the first object, they would notice that all such proposals as those contained in the Eight Hours Bill for miners

were intended once and for all to kill out not only all individual freedom—that every trade union already denied to its members—but all freedom of corporate action to the various trades organisations. The Socialist party consistently rejected all proposals to allow “local option” among trade unions. A striking example was given of this determination of the Socialist leaders for *solidarité* during the discussions in Parliament in November 1893 of an amending Bill on the Employers’ Liability Act. On the Bill being introduced by the Government certain bodies of working men petitioned, through their unions, to be allowed to “contract out,” on the plea that they had with their employers arrangements in existence which gave them superior advantages to those they would gain under the Bill. The parliamentary committee of the Trade Congress raged at their insolence, and under the pressure brought to bear the House of Commons refused to permit “contracting out,” but the House of Lords gave ear to the petition and inserted a clause giving effect to the request. Whereupon the Government withdrew the Bill on the grounds that the measure was rendered distasteful to the trade unions by the permission to contract out. The House of Lords, in fact, went directly in the teeth of that new unionism which was the direct outcome of Collectivism. Nothing was so hateful to the Socialist leaders, because nothing was so detrimental to *solidarité* as independence on the part of working men, and they were specially to be reprobated who raised themselves above their class, or who had special advantages granted to them by employers. Working men under such conditions did not “come to heel” sufficiently abjectly when ordered to do so, and their independence was injurious to the *solidarité* of their class. It was not necessary, surely, to point out how fatal this doctrine which the trade union leaders preached would be to the country. In this country it had been out of the ranks of those who worked with their hands that most of the men had sprung who were the great organisers of labour and the great inventors of machines for the economy of labour. To talk of the capitalist class as if it were a close corporation was nonsense, and pernicious nonsense; the real leaders of the employers in this country at the present time are and always were born in the ranks of the employed; their power came from the intimate knowledge of material they acquired when working at the bench or the loom. The trade of the country would receive a fatal blow if it were not yearly recruited by strong men from the ranks. With regard to the second form of legislative interfer-

CARBOLINEUM AVENARIUS, R^{EGD}. PATENT WOOD PRESERVATIVE.

CARBOLINEUM AVENARIUS, the well-known Wood Preservative, enters the wood by its own action, and does not require a costly plant and machinery like other wood preservatives.

CARBOLINEUM AVENARIUS entirely prevents dampness in brick and stone walls, also wet and dry rot in timber above or below ground, and is used by all the Railway Companies and by leading Builders, Brewers, Contractors, Estate Agents, Mine Owners, &c. in the United Kingdom.

CARBOLINEUM ONLY TO BE HAD FROM

ence, which Socialists at present urged—the throwing on the Government of the country the duty of finding work for the unemployed, of providing for the sick and aged, and of making all education, up to the universities, free—it was not necessary to say much. Each proposal, and every branch of every such proposal, must be discussed on its merits. He would only point out that each act of the Government by which it undertook duties which men could perform for themselves tended to lessen that feeling of independence among the people which was fostered by self-help. The inroad of the State into the province of individual action should be watched with jealous eye. As a sample in a somewhat restricted scale of Collectivism at work, he asked them to consider the actions of the late London County Council. During the last three years the London County Council had been largely controlled by Socialism, and although the Collectivist leaders had not been able to advance very far, they had managed to put at least one of their theories into practice. Their great antipathy was competition and the system of contracts; instead, they proposed that the municipality should conduct its own work in its own workshops, and by means of its own workmen. The London County Council therefore nominated a works committee, which, in the beginning of 1893, took premises in Lambeth for workshops, on which 90,000*l.* were spent. The system pursued was simple, and singularly well fitted for squandering the money of the rate-payers. Say that the committee charged with the fire-engines wished a new station built, instead of advertising for tenders from builders, it applied to the works committee, which furnished an estimate of cost and proceeded with the work. But when the station was completed, and was found to cost 33 per cent. more than the estimate, no one was, of course, to blame, and the poor ratepayer had to "pay the piper." Some of the examples of Collectivist business were very amusing. Hammersmith Bridge required repainting, and in June 1893 the Council empowered the bridges committee to proceed with the work, which the works committee undertook to carry out by means of the corporation workmen for 1,000*l.* The same had been last done for 85*l.*, in 1888, under contract. The accounts for the painting were not presented until January 1895, when they were found to amount to 2,185*l.*—a rise of 150 per cent. on the cost of the work as last carried out. The result was the natural one, seeing that the only persons to be considered were the spenders, and the poor people who had to pay were put out of court

altogether. Another favourite project of the leaders in the County Council was the establishment of municipal bakeries, so that the Council might bake the bread for London, and the ultimate end was the supply of bread by rate, like water, bread and water being the two necessities of life. For this bold project the Council did not live long enough to take even the initial steps. Such were the aims of Socialism, which was exercising a wonderful power over the minds of men. He did not say that the influence of Socialism was altogether for evil, but striking, as it did, at the root of that sense of individuality and moral responsibility, he believed that in the main it was bad. Against the inroads of Collectivism it was their bounden duty as citizens to fight, if they desired the good of the country. But, while he despised the doctrines of Collectivism, he sympathised with the spirit of rebellion against the tremendous inequalities of life, which made Socialists of multitudes who could not understand its doctrines; but in all matters affecting the wealth of nations, the head was a much better guide than the heart, for they could not alter the fundamental principles of human nature, nor the laws which governed the creation and the distribution of wealth. There was a way, however, in which it behoved all who employed working men to combat Socialism—by liberal and honourable and friendly dealing with their workers. It was the old feeling that "wages is no inheritance" which made them Socialists. It was that feeling of rebellion against mere wages which was at the bottom of some of the social unrest. To him it had always seemed wise to recognise that that feeling was just, on the part of those workmen at least who really gave their lives to build up a business. If employers were wise, they had to discover some method of satisfying the working man's desire for some recognition of his real partnership in the concern. Some plan of profit-sharing, or perhaps of commission out of profits for length of service, which in many businesses would not be difficult to put in practice, would take away the ground from below the Collectivist agitators. In concluding, Mr. Harrison said that much as he appreciated the tremendous forces which were working to bring about some social experiment, he denied the likelihood of taking permanent hold on the masses of the country. Its principle was compulsion, and the people of this country had been freemen ever. But Collectivism would bring into being a tyranny to which trades unionism was mild, for the State would be "universal boss," and against the State officials there would be no appeal. Individual action, individual rights, individual conscience

HALLS, SCHOOLS, &c.

SUGG'S

PATENT HIGH-POWER

SUSPENSION GAS LIGHTS,

90 to 600 Candle Power.

ADVANTAGES:—

(1) BRILLIANT, WHITE, SOFT LIGHT.

These lights are fitted with patent *vertical* flat-flame burners, which develop a much higher illuminating power than is obtainable with *horizontal* flames. They are also fitted with Opal Glass Reflectors.

(2) GREAT SAVING OF GAS.

The consumption is far less than under the old system.

(3) NO FLARING OR FLICKERING.

The burners are controlled by a patent Automatic Governor, and the flames are perfectly steady, being protected by the glass screen.

ADOPTED BY MANY LEADING ARCHITECTS.

would be utterly suppressed, and blank uniformity would reign supreme. A great Scottish economist had stated with great clearness how completely the adoption of Collectivism would be fatal to all freedom:—"The real opposite of competition or liberty is compulsion or slavery, the authoritative assignment to each man of the work which he has to do. This is what genuine Socialism, what Collectivism proffers us. It means robbing man of his true self, of what gives to his soul and conduct dignity and worth."

STEAM-ENGINE ECONOMY.

At the ordinary meeting of the Institution of Civil Engineers, on March 19, 1895, the paper read was on "Steam-Engine Economy: Condensing Engines," by Mr. Henry Davey. It was said that the principles upon which the development of the steam-engine as regards economy of steam were founded had been understood in the time of James Watt, who had shown that gain might be expected to result from increased expansion, and had also explained that in order to obtain the full benefit of expansion the steam-cylinder must be maintained at a high temperature. Trevithick, Sims, Grose and others had perceived that increased expansion, and consequently increased economy, might result from the employment of higher pressures. As early as 1844 the Cornish engine had been, for the steam-pressure then practicable, a more efficient engine than any other subsequently produced. Some Cornish engines at that time produced 1 indicated horse-power per hour for a consumption of 19 lbs. of steam at a boiler pressure of 30 lbs. per square inch. Their efficiency was thus greater than that of modern triple-expansion engines giving 1 indicated horse-power per hour with 13 lbs. of steam at a pressure of 120 lbs. per square inch in the boiler. The triple-expansion engine was more economical because it was worked at a higher pressure and at a higher rate of expansion; but it did not utilise the pressure and expansion so efficiently as the Cornish engine had done. A period of sixty-seven years had been required for the development of the principles enumerated by Watt, Trevithick and Grose; and upwards of forty years for the reduction of the consumption of steam from 19 lbs. to 13 lbs. per indicated horse-power per hour, or, in other words, for the diminution of the coal bill by one-third. In these advances no new principle had been applied and no higher efficiency obtained.

The author had collected many examples of steam-engine trials in which the mean indicator-diagrams were available, and the total feed-water per indicated horse-power per hour was known. These he had submitted to analysis to localise the losses. The mean indicator-card of a given trial having been selected, a saturation-curve was delineated to represent an assumed standard for a jacketed engine, working with the steam-engine cycle, and with no losses. This figure having been completed, the losses which make up the difference between the actual and the standard diagram could be readily separated, and their relative importance ascertained. The "engine efficiency" was expressed as the ratio between the mean pressure of the indicator figure and that of the standard engine diagram. The diagrams being drawn to a scale convenient for the use of the planimeter, the area of the waste spaces could be measured and expressed as a percentage of the full area of the diagram. These waste spaces represented cylinder condensation, &c., including condensation in the jacket, clearances, compression influences being taken into account when they were considerable, and back-pressure. Having submitted a considerable number of examples of different types of engines to this method of analysis, the author showed that the economy of steam obtained by modern engines was simply due to increased pressure and increased expansion, and that the engine efficiency or the percentage of work obtained from steam of a given pressure and given rate of expansion, referred to the standard selected, was lower in modern engines than in the Cornish engine thirty or forty years ago. It was also seen that the loss in power arising simply from the cooling influence of the cylinder-walls was not, in jacketed engines at all events, so serious as was sometimes supposed. It was stated that the method gave practical results, and enabled defects in the steam distribution to be readily ascertained; also, that the engine efficiency obtainable from a given steam-distribution afforded a proper gauge of the value of that mode of distribution in point of possible economy. The average engine efficiencies, ratios of expansion and initial pressures for the examples given were:—

	Engine efficiency.	Lbs. of steam per I.H.P. per hour.	Rates of expansion	Initial pressure.
Cornish	73.0	21.0	3.65	33
Single cylinder	66.0	23.5	3.95	76
Compound	64.0	18.5	7.73	84
Triple-expansion	64.4	14.8	14.5	138

The best results in individual cases, fully detailed in appendices to the paper, were much higher.

ECONOMY IN LIGHTING.

A MEETING of the Manchester Association of Engineers was held on Saturday, when a paper on "The economical lighting of public and private buildings, workshops, &c.," was read by Mr. John West, ex-president of the Gas Institute. As the hotel is lighted with electricity the present meeting was held in one of the large rooms of the Central Board School, Deansgate, in order that the paper might be illustrated by experiments. There the Welsbach incandescent gas-burner, regenerator burners, argand and other burners were shown in operation, and remarkable illustrations were given of what is possible in the way of securing a brilliant gas-light. It was explained that the gas supplied throughout the United Kingdom varied in illuminating power from 12 to 28 candles. In many English provincial towns it ranged from 12 to 15 candles; in London it was 16 candles; in Manchester and other places near the canal fields it ranged from 15 to 20 candles; and in Scotland it ranged as high as 28 candles. But in far too many cases the consumer did not get full advantage of the lighting power of the gas. About thirteen years ago Mr. West obtained a large number of the burners in ordinary use in Manchester, and found that the loss of illuminating power by their use came in most cases to over 30 per cent. He feared, from observations he had since made, that that loss was still going on. The best kinds of the ordinary burners were to be had cheap, and in order that there might not be undue pressure of the gas as it issued from the burner, resulting in imperfect combustion and consequent waste of light, he recommended that in private houses a regulator should be attached to each burner, or that what are known as governor burners should be used. For lighting public and private buildings and workshops he strongly recommended the incandescent gas-burner, which, he stated, he was using at his own works, with the result that he obtained at half the former cost four times more light. Alike in public and private buildings, where general lighting was desired, he recommended that the chandelier or pendant should be placed in the centre of the building or room, as where brackets were used the walls absorbed a great quantity of the light. Comparing the cost of incandescent electric-lighting with the cost of incandescent gas-lighting, he stated that a 16-candle incandescent electric lamp in use 1,000 hours would absorb 60 units of electricity, which, at 6d. per Board of Trade unit, would come to 30s., whereas an incandescent gas-burner consuming 3 cubic feet of

gas per hour, or 3,000 cubic feet in 1,000 hours, and giving a light equal to that of 60 candles, or fully three times that of the electric light, would cost, with gas at Manchester at 2s. 3d. per 1,000 cubic feet, 6s. 9d.; at Maidstone, with gas at 2s. 4d. per 1,000, 7s.; and at Plymouth, with gas at 1s. 9d. per 1,000, 5s. 3d. He challenged the electricians to disprove those figures.

PATENTS.

NEW READING CASE.

To Librarians of the Public Libraries and Reading-rooms.—A new handsome Reading Case can be supplied at a nominal charge of 2s., by post 2s. 6d., on early application to the Publisher, 175 Strand, W.C.

SPECIAL NOTICE TO THE TRADE AND OTHERS.

[Extract from a lecture on Architects' Libraries by Professor T. Roger Smith, F.R.I.B.A., at University College, October 10, 1893.]

"Lastly, let me recommend the back volumes of the professional journals. In the course of years all sorts of architectural topics come up in the public press and before the professional societies, and if you hunt through the indexes of these publications when you are seeking for information which eludes you in books, you will often be rewarded."

There has been a considerable demand for the back numbers of *The Architect* during the last three or four months, which we have no doubt has arisen from the remarks made by Professor Roger Smith, as contained in the above quotation; but the consequence has been that our stock of back numbers is getting very low, and consequently, in future, the charge for back numbers of previous date to January 12, 1894, will be 6d. each.

A few of the back volumes may still be had, price 12s. each.

EDITORIAL NOTICES.

The authors of signed articles and papers read in public must necessarily be held responsible for their contents.

No communication can be inserted unless authenticated by the name and address of the writer—not in every case for publication, but as a guarantee of good faith.

Correspondents are requested as much as possible to make their communications brief. The space we can devote to Correspondence will not usually permit our inserting lengthy communications.

TENDERS, ETC.

*** As great disappointment is frequently expressed at the non-appearance of Contracts Open, Tenders, &c., it is particularly requested that information of this description be forwarded to the office, 175 Strand, London, W.C., not later than 5 P.M. on Thursdays.*

COMPETITIONS OPEN.

BRIGG.—April 19.—Designs are invited for Scheme for Sewerage and Sewage Disposal. Mr. G. S. Sowter, Urban District Council Offices, Brigg, Lincolnshire.

KIRKCALDY.—May 1.—Plans are invited for proposed Infectious Diseases Hospital. Town Clerk, Kirkcaldy.

LLANELLY.—May 15.—Elevations and Plans are invited for proposed School. Mr. Fred. Nelson Powell, Clerk to the Managers of the Llanelly Intermediate and Technical Schools, Llanelly.

CONTRACTS OPEN.

ABERTILLERY.—April 15.—For Building Schools. Mr. Geo. Rosser, Architect, Victoria Buildings, Abercarn.

BELPER.—April 20.—For Alterations and Additions to Lock-up. Mr. J. S. Storey, County Surveyor, Market Place, Derby.

BILSTON.—April 16.—For the Reconstruction of Baths. Mr. Wilson, C.E., Town Hall, Bilston.

BRAINTREE.—April 18.—For Erection of Casual Wards, Board and Committee Rooms, &c. Mr. Frank Whitmore, Chelmsford.

BUILTH.—April 24.—For Constructing Reservoir, Filter-bed, &c. Mr. R. L. Bamford, Widemarsh Street, Hereford.

CAMBRIDGE.—April 23.—For the Supply of Manhole and Ventilator Covers, Valves and Other Castings for Main Sewerage Works. Mr. John T. Wood, A.M.I.C.E., 3 Cook Street, Liverpool.

CAVERSHAM.—April 19.—For the Construction of Sewerage Works. Mr. Nicholson Lailey, F.G.S., 18 Great George Street, S.W.

CHELSEA.—April 23.—For Painting Outside Workhouse. Messrs. Lansdell & Harrison, 12 Compton Terrace, N.

CITY OF LONDON.—April 30.—For the Construction of Underground Conveniences in Circus Place, Finsbury, and Cannon Street. Mr. H. Montague Bates, Tenders Office, Guildhall.

DARENTH.—April 17.—For the Erection of a Board School for 220 Children, with Boundary Wall or Fence. Mr. W. J. Judge, Horn's Cross Stone, Greenhithe, Kent.

DINGWALL.—April 22.—For Repairing Roads. Mr. A. G. Joass, Surveyor, Dingwall, N.B.

DUBLIN.—April 15.—For Building Railway-station Offices, Waiting-rooms, &c. Mr. W. H. Mills, Amiens Street Terminus, Dublin.

GOSFORTH.—April 23.—For Extending Asylum. Mr. John W. Dyson, Architect, 18 Grainger Street, Newcastle-on-Tyne.

GREAT YARMOUTH.—April 12.—For Building Water Tower. Mr. D. Palmer, 38 Hall Quay, Great Yarmouth.

HENDON.—April 22.—For Excavating, Forming, Levelling, Metalling, Kerbing, Channelling, Tar-paving, Construction of Gullies, &c. Mr. S. S. Grinsley, The Burroughs, Hendon.

KETTERING.—April 22.—For Constructing Service Reservoir. Mr. T. Hennell, 6 Delahay Street, Westminster.

LEEDS.—April 13.—For Supplying and Erecting Six Purifiers. Mr. R. Smith, New Wortley Gasworks, Leeds.

LITTLE LOCH CRAIGNISH.—April 16.—For Constructing Pier. Mr. G. Woulfe Brennan, Engineer, Oban.

LONDON.—April 17.—For Supplying Aberdeen Granite Cubes. Mr. W. H. Atkins, Board of Works Office, Bank-side, S.E.

LONDON.—April 23.—For Erection of a Timber Shelter in Clissold Park and Two in North Woolwich Gardens. Mr. H. De la Hooke, London County Council, Spring Gardens.

LURGAN.—April 18.—For Building Business Premises. Mr. Henry Hobart, Architect, Dromore, Co. Down.

MANCHESTER.—April 15.—For the Supply of 500 Tons of Bessemer Steel Tram Rails, Fishplates, &c. Mr. William Henry Talbot, Town Hall, Manchester.

MANCHESTER.—April 18.—For Alterations and Additions to Horse Hospital. The Engineer, Manchester, Sheffield and Lincolnshire Railway Company, London Road Station, Manchester.

MERTHYR TYDFIL.—April 18.—For Building Thirty-two Houses. Mr. John Williams, Architect, Morgan Town, Merthyr Tydfil.

MIRFIELD.—April 19.—For Building Two Detached Houses and Eight Cottages. Mr. Reuben Castle, Architect, Westgate, Cleckheaton.

MORLEY.—April 13.—For Building School. Messrs. Holtom & Fox, Architects, Dewsbury.

MORLEY.—April 13.—For Pulling-down and Rebuilding Three Houses and Shops. Mr. T. A. Buttery, Architect, Queen Street, Morley, Yorks.

NEWCASTLE-ON-TYNE.—April 23.—For the Erection of the Superstructure of the Extension of the City Asylum. Mr. John W. Dyson, 18 Granger Street, Newcastle-on-Tyne.

PENRITH.—April 15.—For Constructing Waterworks. Mr. C. N. Arnison, Rural District Council Offices, St. Andrew's Place, Penrith.

PORTSMOUTH.—April 17.—For Making Roads. Mr. A. Hellard, Town Hall, Portsmouth.

ROCHESTER.—April 17.—For Making up Roads. Mr. William Banks, Guildhall, Rochester.

ROTHERHITHE.—April 20.—For the Erection of Staff Quarters. Mr. T. W. Aldwinckle, 1 Victoria Street, S.W.

RUABON.—April 12.—For Building Court-house. Mr. R. Lloyd Williams, County Surveyor, Denbigh.

SENGHEWTH.—April 13.—For Building Hotel. Mr. E. H. Burton, Architect, 15 Queen Street, Cardiff.

SOUTHGATE.—April 19.—For the Supply and Delivery of 1,500 Tons (more or less) of Hand-broken Granite, the carting thereof from the railway stations to various points in the district, Glazed Fireclay Pipes, Pipes with Special Watertight Joints, Portland Cement, Iron Castings, &c. Mr. W. M. Ellenor, Council Offices, Palmer's Green, N.

SOUTHWARK.—April 17.—For the Supply of 300 Tons Aberdeen Granite Cubes and 36,000 Jarrah Wood Blocks. Mr. W. H. Aikens, Board of Works Office, Emerson Street, S.E.

STEEPLE CLAYDON.—April 23.—For Building Schools, &c. Messrs. George Bennett & Sons, Surveyors, Buckingham.

STOCKPORT.—April 22.—For Constructing Brick Sewers, Cast-iron Culverts, &c. Mr. A. M. Fowler, 1 St. Peter's Square, Manchester.

THORNHILL.—April 16.—For Constructing Pipe Sewer. Mr. James C. Haller, Council Offices, Thornhill, Yorks.

TUNBRIDGE WELLS.—April 26.—For the Erection of a Post Office. Messrs. Lee & Sons, 35 Craven Street, W.C.

WARRINGTON.—April 15.—For Supplying Granite Cubes, Chequered Tiles and Blue Bricks. Mr. T. Longdin, Town Hall, Warrington.

WELLINGBOROUGH.—April 16.—For Supplying Granite. Mr. Willan Jackson, Workhouse, Wellingborough.

WEST HAM.—May 14.—For Two Beam Pumping-Engines, each about 250 Indicated Horse-power; Two Centrifugal Pumps and Engines, each about 350 Indicated Horse-power;

Four Boilers, each 30 Feet in Length by 7 Feet 6 Inches in Diameter; also Alterations to Existing Centrifugal Pump, Engine and Boilers and Other Works. Mr. Lewis Angell, Town Hall, Stratford.

WIMBLEDON.—April 23.—For the Erection of a Caretaker's Cottage. Mr. W. H. Whitfield, Broadway, Wimbledon.

TENDERS.

VARIETIES.

THE Buckingham Town Council, at their meeting held on the 1st inst., decided to adopt the recommendations of the committee and to instruct Mr. H. Bertram Nichols, C.E., of Birmingham, to prepare a pumping scheme of sewerage for the town on the lines laid down by him, and to submit the same within a fortnight to the Grand Junction Canal Company, so as to comply with the arrangement entered into by Mr. Higgins, Q.C., on behalf of the Council.

THE drainage of the eastern block of the Royal Courts of Justice is now being entirely reconstructed and replaced, and will take some months to finish. With the completion of this part of the building the whole of the drainage of the Law Courts will have undergone a thorough overhaul, and when finished all the latest sanitary appliances will have been provided for the various lavatories, &c. More direct access to the waiting-rooms for witnesses and others will shortly be provided by the construction of doors leading straight from the court corridor to these rooms. The first one to be opened out will be between Queen's Bench Court 9 and Probate Court 1, and will be cut through the stone wall of the court corridor.

ONE of the inspectors of the Local Government Board has held a series of inquiries into applications of the Manchester City Council to borrow sums amounting in the aggregate to more than 260,000l. Of this, 100,000l. was for the extension of the electric-light system in the city, 100,000l. for works of sewerage and sewage-disposal, 50,000l. (in excess of present borrowing powers) for the building of the technical school, and 10,000l. for the replacing of defective drains in the poorer parts of the city.

AT the meeting of the Airdrie Town Council it was announced that Mr. Alexander, of Airdrie House, offered to present the town with the Mill Field, as a public park for the town. The ground extends to nearly eight acres, and is in a central position.

AT the meeting of the Association of Birmingham Civil Engineer Students, held under the presidency of Mr. Robert Godfrey, Mr. H. C. Adams, hon. secretary, read a paper from Mr. H. H. Marsh on "The Relative Efficiency of Round, Flat and other forms of Tie Rods in Roofs." Mr. Marsh dealt with the three commonest forms of roof principals, namely, (1) with the tension principals composed of round rods; (2) with the

ANTHYDOR.

TELEGRAPHIC ADDRESS, "WEATHERWISE, LONDON."

As supplied to Her Majesty's Government, London County Council, Midland Railway, &c., &c.

A High-class Paint for Outside and Inside Walls and Ceilings of Public and Private Buildings, Government Offices, Banks, Colleges, Schools, Warehouses, Offices, Railway Stations, Factories, Asylums, Hospitals Churches, Chapels, Cottages, Coach Houses, Laundries.

It will cover on Brick, Plaster, Stone, Cement, Wood, Iron, and Metals of all descriptions.

A HIGH-CLASS PAINT FOR DECORATIVE ART WORK.

REQUIRES NO SIZING, IS WASHABLE, VARNISHABLE, IMPERISHABLE.

WILL KEEP ANY LENGTH OF TIME.

Works very FREELY and covers EVENLY. It only requires thinning with TEPID WATER. Its covering properties are nearly half as much more than any other Paints or Distempers.

ANTHYDOR COMPOUND & GENERAL PAINT CO.

LIMITED,

47 VICTORIA STREET, WESTMINSTER, S.W.

tension principals composed of flat bars; and (3) with the tension principals composed of angle bars. Having given a detailed description of each of the three types and a comparison of their relative weights and cost, he said that in buildings where appearance was the chief consideration, as in public buildings, type 1 recommended itself; in cases where first cost was the primary object, and where the principals themselves were not subjected to lateral wind pressure, type 2 should be used; but in sheds which were open, and therefore exposed to the force of the winds, type 3 was most suitable, owing to its great lateral stiffness.

THE Bill promoted for the purpose of establishing a new cattle market at Bootle, Liverpool, with railway approaches and landing stages at the north end of the Mersey, for the accommodation of the Irish cattle trade, has passed the select committee of the House of Commons. The capital of the new company incorporated under the Bill is 400,000*l.*, a third of which sum is to be expended on the new market, and the remainder on general improvements.

AT the meeting of the Greenock School Board it was stated that plans had been received from nine architects. Much consideration had been given to the plans, but probably professional assistance will be called in before a decision was arrived at.

THE *Irish Times* says:—The Youghal Town Commissioners have decided to contribute a sum of 1,000*l.* towards the fund for the erection of a barrier against the encroachments of the sea, and the committee of the Cork Grand Jury have expressed a favourable opinion on the subject, and will report to the grand jury at summer assizes. Mr. Kirby, county surveyor, has prepared a map showing that should the sea break in permanently, it would cover an area extending at least three miles in length, covering all the roads in the vicinity and portion of the main road to Cork. The Town Commissioners have appointed a deputation to wait on the directors of the Great Southern and Western Railway Company with reference to the contribution of the company to the project.

AT the meeting of the East of Scotland Engineering Association, Mr. William Simpkins, president, in the chair, Mr. Edgar H. Fairgrieve read a paper on the "Stability of Voussoir Arches," in which he described the principles involved and the necessary conditions for attaining stable equilibrium in the different forms of arches, abutments, piers, &c. He showed graphically how the linear arch for any load can be

drawn, and the application of graphic statics generally in the treatment of the subject.

AN inquiry has been held by the Local Government Board in respect of two applications for borrowing powers made by the Southport Town Council. The first was in respect to a sum for foreshore improvements. For the construction of a marine drive and the connection of the two lakes the Corporation had been empowered to borrow 20,000*l.* They now proposed to lengthen and raise the bridge over the junction of the lakes, so as to make one continuous slope from the Promenade, and this and other work which the alteration involved would cost 8,500*l.*, for which they now applied. The second application related to the electric-lighting system, which was put into operation last November. The present borrowing powers amounted to 28,000*l.*, of which they have already expended 18,746*l.*, leaving a balance of 9,254*l.* Already more than 2,000 lamps were wired on the mains more than the generating plant could really supply, and the electric-lighting committee proposed to extend the buildings and power of the station to meet the present growing demand and to enable them to tap the residential district of Hesketh Park. The cost of this work was estimated at 21,250*l.*, and over and above the balance in hand they applied for power to borrow 12,000*l.*, in addition to 3,500*l.* for street arc lighting, making 15,500*l.*

AT the meeting of the Walsall Town Council, the health committee reported that a house-to-house inspection of 1,633 houses in 33 streets in the town had been made; and that they had under consideration the draft plans prepared by the borough surveyor for the proposed epidemic hospital, but, having regard to the great cost of carrying out the same, they had requested him to prepare modified plans so as to reduce the cost.

THE death has occurred of the burgh surveyor of Gourrock, N.B., who was held in the greatest esteem by all the community.

THE death is announced of Mr. T. C. Wakeling, architect, at Merthyr, having by mistake taken an overdose of chloral.

IN consequence of the enormous increase in the tobacco imports, the Mersey Docks and Harbour Board are considering a new scheme to meet the warehousing requirements of the tobacco trade.

THE Greenock School Board, considering that public baths are required, and in default of town baths being provided, propose to erect baths in connection with the schools.

WINSOR & NEWTON'S "Waterproof" INDIAN INK.

This new preparation—made from genuine Indian Ink—has been introduced to meet the requirements of those Artists, Architects and Designers who wish to lay washes of colour over drawings in ink.

Unlike many so-called Indelible Inks, "Waterproof Indian Ink," when dry, will be found absolutely unaffected by subsequent wetting.

The leading features are:—

- EXTREME FEWNESS OF PARTS.
- THE ABSENCE OF FANS, PUMPS, &c., for starting.
- THE ABSENCE OF AIR AND OIL PUMPS for introducing the charge.
- THE RELIABILITY IN WORKING under varying loads.
- THE SUITABILITY for working with ordinary petroleum (paraffin lamp) oil.

TANGYES LIMITED,
BIRMINGHAM,

London, Newcastle, Manchester Glasgow, Sydney, Johannesburg, Bilbao, and Rotterdam.

THE spring meeting of the Iron and Steel Institute will be held in London on Thursday and Friday, May 9 and 10 next. The building operations at the Civil Engineers' rooms will prevent the meeting from being held at their house as has been the usual practice, and it will accordingly be held at the rooms of the Society of Arts. The presidential address will be delivered by Mr. David Dale, and the Bessemer gold medal will be awarded to Mr. H. M. Howe. Mr. Herbert Scott will communicate a paper on the iron ore mines of Elba; and Mr. W. J. Keep, of Detroit, U.S.A., will contribute a paper on tests of cast-iron.

THE annual general meeting of the London and Lancashire Fire Insurance Company will be held on Thursday, April 25, at the Law Association Rooms, Cook Street, Liverpool.

TRADE NOTES.

THE Borough Cemetery Chapels, Nelson, are being warmed and ventilated by means of Shorland's patent Manchester grates, the same being supplied by Messrs. E. H. Shorland & Brother, of Manchester.

WE learn that Messrs. Charles Tighe & Sons have granted to Messrs. Chubb & Sons, of Queen Victoria Street, E.C., the sole right to manufacture and sell the patent door furniture, and they will be obliged if all orders in future are sent direct to them.

WE hear that Mr. R. Merton Hughes, builder and contractor, Birmingham, has obtained the contract for the Bridgworth and South Shropshire Infirmary at Bridgnorth, Mr. Edward C. H. Maidman, architect, 1 Comely Bank Avenue, Edinburgh, and quantity surveyor Mr. W. E. Davis, Falcon Court, 32 Fleet Street, E.C.

A TENDER has at last been accepted for the erection of a free library at Abingdon. Mr. J. G. T. West, of Abingdon, is the architect. The Governors of Christ's Hospital have accepted the tender of Mr. Grant, of Banbury, at 1,848*l*. The highest tender amounted to 2,435*l*.

A FIRM in Leeds have lately been devoting attention to the production of scagliola work, in imitation of marble, for decorative purposes in interiors.

WE are informed by Mr. A. C. Motte that he is no longer with Messrs. W. Walker & Sons, of Bunhill Row, E.C., having entered into an engagement with Messrs. S. J. Waring & Sons, Limited, of 181 Oxford Street, W. (also of Liverpool and Manchester), general house furnishers and decorators, and probably the largest manufacturers of high-class cabinet and interior woodwork.

BUILDING AND BUILDERS.

AT the meeting of the Prescott Guardians it was agreed that the new infirmary should be built on the Holt estate, near the present building. Mr. Gandy is the architect carrying out the scheme; it will cost about 24,000*l*.

THE sub-committee of the Glasgow Corporation have recommended the erection by the Corporation of tenements of shops, warehouses and dwelling-houses in Trongate, King Street and Parnie Street, to the aggregate value of 29,000*l*.

THE Helensburgh authorities intend to borrow 1,200*l* for reconstruction of sewers.

THE executive committee of the Association for the Promotion of Art and Music in the City of Glasgow have received from the architects a report on the progress of the Art Galleries in Kelvingrove Park during the month of March. In the central block the outer walls at the north end are up to the window heads. The main towers are nearly up to the stipulated height, and the building of piers and walls at the south end is in progress. The iron stanchions required for same have come to hand. In the east wing the southern outer wall is up to the required height, and in this wing and the western wing the glazed brickwork in areas and lavatories is being proceeded with.

THE *Leeds Mercury* says:—The late Mr. Scott, of Hunslet, a well-known worthy, who died some little time ago, left in his will 10,000*l*. to provide almshouses for ten deserving poor people resident in that township. One-half the sum was to be spent in the purchase of a site and the erection of the buildings, while the other half was for an endowment, which it is now expected will provide 8*s*. per week for each person. The necessary land has been secured at Woodhouse Hill, Hunslet, and the plans have been prepared by Mr. John E. Leak, architect, Waterloo Road, Hunslet, and are now before the building committee of the Leeds Corporation awaiting their approval.

"MANCHESTER" DYNAMO.

ELECTRICAL.

THE tender of the Thomson-Houston Company has been accepted by the municipality of Paris for their overhead electric tramway system in some of the outskirts of the city, and for their culvert system in the narrower streets running towards the centre of the city. The Thomson-Houston Company have made arrangements for the manufacture of all their machinery and appliances for use in the United Kingdom by Sir W. G. Armstrong, Mitchell & Co., Limited, of the Elswick Works.

AT the meeting of the Hull Town Council, Dr. Holder, moving the adoption of the committee's minutes, urged that that portion recommending that specifications for the new engine, dynamo, boiler and switches, instruments, &c., and that quotations be obtained, be approved. Discussion ensued, and members spoke strongly in favour of keeping the work in the town. It was suggested that tenders should be invited from local firms for such portions of the work as could be done in Hull.

MR. HENRY HARBEN, of Hampstead, has decided to erect at his own expense a building at Littlehampton, to cost 20,000*l.* The home will contain reading-rooms, &c., and all the latest improvements, and will be lighted throughout by electricity. The work will be put in hand forthwith. Mr. Wheeler is the architect.

THE BUILDING EXHIBITION.

AMONGST the exhibits not yet noticed,

Thwaites Bros., Limited,
of the Vulcan Ironworks, Bradford, showed an Andrew-Howatson patent diurnal water softener, capable of softening 1,000 gallons of hard water per hour, models of Andrew-Howatson softeners and filters.

C. Davidson & Sons, Limited,
of Paul's Pier Wharf, London, showed their roofing and foundation felts.

Skey & Co., Limited,
of Tamworth, showed a large selection of sanitary appliances, &c.

Wybrow's Fire-escape Balcony Staircase Company,
Birmingham, showed a model of Wybrow's fire-escape balcony staircase, constructed for palaces, mansions, theatres, hotels, asylums and warehouses.

John Line & Son,
of Aldersgate Street, E.C., and Reading, showed a quantity of artistic wall-papers, among which were included the Anaglypta wall-papers and Lincrusta-Walton wall-papers.

Arthur Lee & Bros., Limited,
of Bristol, samples of white and coloured marbles in ordinary use for decorative purposes, photographs of marble works executed at the Clifton Pump Room, designs for marble mosaic floors, and samples of marbleised slate.

Corporation of the City of London.

At this stand was shown a quantity of illustrations of the many works designed and carried out in the City of London by the late Horace Jones, City architect, and also one by J. B. Buning. A model of the new council chamber at the Guildhall was also shown.

Royal Institute of British Architects.

The display at this stand did not fulfil the expectations that might have been formed, the loan collection of drawings not being of the best. If we remember rightly, many interesting specimens of old wood-carving lent by Professor Banister Fletcher, were shown. At several other stands could be seen other specimens of old wood-carving lent by the same gentleman.

Among other exhibitors Messrs. Samuel Wright & Co., specimens of fibrous plaster enrichments; Robson & Co., Sunderland, a ventilator; the Mechanical Inventions Syndicate, Limited, door check and spring; R. & J. Dick, of Glasgow and London, their Balata driving-belts; J. C. Broadbent & Co., silicate cotton or slag-wool; S. J. Wiseman, Southampton, ventilating window, door and casement-fasteners; H. J. Skelton & Co., sections of rolled steel joists, girders, &c.; J. J. Hopkins, West Brompton, Staffordshire, blue bricks and tiles, Broseley roofing tiles, &c.; J. Duckett & Son, Limited, of Burnley, various of their sanitary specialties and appliances; A. C. W. Hobman, a number of articles in mosaic and Clifton stone; W. Garstin & Sons, marblework and also leaded granite concrete; C. Beale, of Eltham, red pressed bricks, ridge tiles and other pottery; S. A. Macfarland, statuary for monumental purposes; Morgan & Co., reversible windows and casements; C. H. Wilkinson, venetian blinds.

Mr. H. Spear, morticing and tenoning machines, circular saws for iron and wood, and saws of all other kinds, including hand-saws; T. Middleton & Co., a combined brick, tile and

pipe machine; Pullan & Mann, Leeds, screw brick and tile press, with patent power driving gear; Samuel Jefferies, Dudgeon, Stroud, automatic brick-cutting tables; West's Patents Syndicate, Limited, moulding machines for domestic and garden pottery; Wm. Johnson, Armley, dry press brick-making and pressing machine. Some half a dozen firms showed models of their continuous kilns.

Several lectures and conferences were held at the Hall, which took place during the afternoons. The first of the lectures was by Professor Banister Fletcher on the "London Building Act;" a second by Mr. Henry Ansell on "Glazed Brick-making;" "Comparative Architecture," by Professor Banister Fletcher; "British & American Brick-making," by Mr. Alfred Crossley; "Chemical Aspects of Clay-working," by Mr. J. T. Norman; and "Electricity applied to Public and Private Buildings," by Professor Henry Robinson.

The Exhibition was each day enlivened by a concert which was, for the first week, under the able direction of Miss Lilian Clausen, whose ladies' orchestra, known as the Pompadour Band, and consisting of some eighteen fair performers, richly attired in the picturesque costume associated with the sprightly favourite of Louis XV., played a varied selection of pieces with a *verve* and precision which reflected the greatest credit on their talented conductor. Miss Clausen's company, being "booked" for the provinces, was replaced during the second week by Mr. Glenn-Wesley's concert company, which comprised Madame Jessie Strathearn, silver medallist R.A.M. (soprano), Madame Joyce-Maas, who, we are informed, is a sister of the late celebrated tenor (contralto), Messrs Henry Slaughter and Arthur Barlow (tenor and baritone). The programme, if it did not present any striking novelties, was sufficiently varied, and the items of which it consisted were artistically rendered, and received with evident pleasure by an appreciative audience. Indeed on Thursday—the last night of the Exhibition—the company got quite an ovation. Madame Strathearn, whose performance was undoubtedly the best of the evening, received a double recall for both her songs, Adams's "Star of Bethlehem" and Levey's "Esmeralda," an honour which was also accorded to Madame Maas for her rendering of "The Better Land," while the gentlemen were equally well received. In addition to the vocal items, Mr.

H. Distin gave two well-rendered *solis* on the cornet, Hatton's "To Anthea" and "Solitude," by the conductor, Mr. Glenn-Wesley.

The Duke of Fife on Thursday night in last week presented silver and bronze medals and certificates to the workmen who were successful in the handicrafts competition held in connection with the Building Exhibition at the Agricultural Hall. Among those present were Professor Fletcher (who presided), Mr. Preston (past master of the Carpenters' Company), Mr. Gilbert Wood, Mr. Blashill (architect to the London County Council), Mr. Benedict, C.E., Mr. Porter and Mr. Montgomery (the organiser of the exhibition). The Chairman said the competitions had been one of the principal objects of the exhibition. Thirty-nine workmen competed, the trades represented being those of the bricklayer, carpenter, joiner, mason, painter, decorator, plasterer, plumber, tile-fixer and modeller. In the opinion of the judges these competitions and the technical education now being so largely imparted would not only become, to some extent, a substitute for the fast-dying system of apprenticeship, but would help the workmen of this country to more than hold their own against foreign competition. The awards having been distributed, a vote of thanks was, on the motion of Mr. Gilbert Wood, seconded by Mr. Benedict, passed to the Duke of Fife, who, in reply, remarked upon the fact that the comfort of every one—rich or poor—depended in a large measure on the building trade. It was therefore essential that the workmen connected with this industry should be thoroughly masters of their work. These competitions popularised good work and raised the standard of labour.

NEW CATALOGUES.

THE catalogue we have received from Messrs. Nettlefold & Sons, of High Holborn, which we recently referred to, is excellently printed and nicely bound in red cloth. It is copiously illustrated throughout, and it forms a very exhaustive compilation on general and builders' ironmongery. It will be found extremely handy for reference by architects and builders. Those engaged in building operations have a definite idea of

what is required for any particular purpose, and will find a great choice afforded them under every kind. The articles that come under what we may term lock and door furniture are simply legion. But when every week sees some article improved or some new article invented, the reason must be that new wants arise or that older fashions have been improved to meet new requirements of buildings. To classify the various kinds of buildings by name would be an arduous task, and a list of them would take up much space. There are residential houses, mansions, halls, villas, cottages—such are the names of a few of our dwelling buildings. There are churches, schools, business premises of every kind, stables, factories, institutions of all descriptions. The smallest of buildings, a cottage for instance, has many doors, windows, including cupboard doors which cannot serve a useful purpose till fitted with locks, hinges, bolts, handles, &c. There is not only a variety to choose from for each class of building, but as the kind of building differs, there is a variety from which to select in each case. The door furniture—most excellently designed, as seen by the engravings in the catalogue—is ornamental. Even the plainest description can contribute its quota in this respect. The designer is also greatly helped out by the qualities of the materials he can work in. As to woods, there is oak, ebony, rosewood, walnut, maple and many other high class woods. Glass also is employed most effectively, and when metal is employed there is unlimited scope for a skilful designer. The chief door, or as it is usually called, the front door of a building, has its own additional variety of fittings—knockers, bell-pulls, letter-box fittings, &c. Space will not allow of giving more than the above notice of this catalogue, and even in our reference to door furniture allusion has not been made to a tithe of the articles. We must refer our readers to the catalogue. Any of them who are not engaged in building operations, if they take a mental tour of their houses and offices from top to bottom, will gain a very good idea of the legion of articles that have been made use of to render the building complete.

THE immense development that has taken place of late years in applying electricity to so great a number of uses is amply shown by glancing over the catalogues of Mr. G. Straus, of 130 Queen Victoria Street, E.C., which give a good idea of the numberless fittings, &c., that are required for putting electricity to practical purposes. "Apparatus and Accessories for Telegraphs, Telephones and Lightning Conductors" is the title of

the two lists, the second of which is supplementary to the first. In the space at our disposal we confine ourselves to calling attention more particularly to the bells and telephones and their accessories. The electric bells can be had in various excellent kinds increasing in superior quality. Different kinds of bells also serve to meet different purposes. Some have the automatic interrupter, others are furnished with an indicator disc. Then there are the continuous action bells and also electric bells specially made for fixing in the open air, portable electric bells, &c. Special attention should be called to Nos. 533, 1,660 and 1,670 (telephones). There are also new designs in bells, and among them we may refer our readers to the one illustrated in Nos 850 and 851 in connection with a dry battery, forming an exceedingly original and convenient form of portable bell sets.

MALTON CHURCH.

A NEW pulpit and baptismal font have been recently erected in the Catholic church, Malton. The pulpit is of Caen stone, and is in the thirteenth-century style. The front is divided into five panels, with coves and angles, showing beaded mullions and arches over arches deeply sunk, with plate tracery, trefoils, quatrefoils, &c. There is an ornamental book-rest, supported by moulding from mullions and cornice above. The sides are pierced, and show beautiful examples of bar tracery, to correspond with the front. These are draped with crimson tapestry from the sill to the handrail, and are divided into openings the same as the front and richly decorated. There are two plain panels between plinth and string, which are left for carving to be done hereafter. The pulpit is fixed against the south wall of the church, immediately outside the communion-rail, and is entered from the sanctuary between two ornamental pillars. The work has been executed by Mr. Anthony Lyons, builder, of Norton, near Malton. The baptismal font, which harmonises admirably with the altar, pulpit and other architectural features of the church, is the gift of Mr. A. Lyons. The base is of Robin Hood stone splendidly polished. The shaft and capital is of Roche Abbey magnesian limestone, circular and moulded. The font itself is of Carrara marble, octagonally shaped. The lid, of dark brown oak with brass fittings, assumes the form of a cone, surmounted by a cross. It stands in the south-west corner of the church, and has the following inscription carved on the base, "Ex dono Antonii Lyons, A.D. 1895."

SAND BLAST PROCESSES.*

A PAPER on the sand blast was read in this room by Mr. William E. Newton, in February 1875. The invention was then in comparative infancy as regards apparatus and its practical applications in manufactures and the arts. Notwithstanding its continual developments in both particulars, the sand blast is still not popularly known; it is considered that something more may now be said on the subject.

The sand blast was invented by Mr Benjamin Chew Tilghman in 1870, and, stated shortly, consists of a stream of sand or other abrasive powder, usually dry, but sometimes mixed with water, projected with more or less force and velocity to strike and pulverise the surfaces of glass, stone, metal and other materials upon which it is directed.

It has been frequently pointed out that, in this invention, Mr. Tilghman has really borrowed or adopted from nature herself, inasmuch as he has intensified and put to use a natural force of which the effects are always apparent under favouring conditions; that is to say, wherever we find large deposits of loose sand exposed to prevalent winds, by which the sand is caught up and blown against any hard substance, such, for example, as the glass in a window, which soon becomes depolished and obscured by the contact of the sand; or stone, the surface of which, with time, is sensibly roughened and sometimes scored in a manner quite distinct from ordinary weathering.

The abrasives used in the process include ordinary inland silicious sand, sharp builders' sand, powdered glass, emery, from fine to coarse, chilled iron sand and steel shot; and the streams of these powders are forcibly projected through

variously formed nozzles by means of steam, by currents induced by exhaust air, by blasts of air, and latterly and more conveniently, by compressed air. Sand, from its plenteousness and general suitability, is mostly employed; that used in London comes from Reigate, and when freed of pebbles and impurities is again sifted into several sizes for different classes of work.

Grains of sand have numerous angles, and the action of these grains—as also that of the other abrasives mentioned—upon the surfaces of glass, stone or metal is due to the circumstance that every individual grain in the incessant infinite number in the stream urged violently forward has all its energy instantly arrested, transferred and concentrated upon its point of impact, where it produces a minute pit or depression; and as every grain in the shower acts alike, the abrasion resulting from the whole is perfectly uniform in depth and texture or roughness.

The action, moreover, is extremely rapid; as you will see later, a momentary application depolishes glass over any space that can be covered by one stroke of the sand shower, instantly changing the previously bright surface to obscured, or that known as ground glass. A little longer exposure cuts more deeply, and, with further time, apertures are readily pierced through sheet and plate glass.

Stone, marble, slate and granite are just as amenable to its action. Iron, steel and other metals have their surfaces easily reduced, and smoothly or coarsely granulated, according to the force and abrasive powder used; but all these materials, being less brittle than glass, take a rather longer time. Speaking generally, it appears that the harder or more dense the material acted upon, and the higher the velocity given to the sand, the more rapid the cutting action; and the finer the abrasion, and the lower the pressure of the air or steam, the finer the granulation produced. It is also remarkable that it is by no means necessary that the abrasive be harder than the material to which it is applied, thus hardened steel and corundum are readily pierced with sand.

This granulating, scaling, incising and piercing, however, is but one-half of the process, for if the work be partly covered and protected by some slightly yielding but tough substance, adhesive, or in the form of a metal template lying closely upon it, this interposed substance instantly diffuses the shock of the particles and neutralises their abrasive power. The action of the sand blast is thus confined to the unprotected portions of the surface, and these overlays and templates are used on

glass, stone, slate, pottery and metal for surface ornamentation, for deeper intaglio and perforations.

All results from the sand blast arise from the cumulative action of the immense number of grains of the abrasive powder striking the surface; but the impact of every individual grain does but an infinitesimal portion of the work; hence, as unusual as important, the very rapid erosion is really most gentle in character, with total absence of risk of damage to the material, however fragile, as for example the splaying or chipping of edges met with in carving stone by hand.

The sand blast is in constant use for obscuring or producing a uniform granulation known as ground glass, on sheet glass, lamp globes, the bubbles for incandescent lights and the like; for the decoration of sheet or objects in glass with ornamental designs, in which the pattern or the field may be left bright and transparent, of which there are numerous varieties, one being on glass of two or more thicknesses of different colours, to leave the design of one colour on a field of another; for the decoration of glass table-ware, and the labelling of measures, chemists' and other bottles. Several examples lie on the table.

In metal, for the removal of the hard scale, so destructive to cutting tools, from castings and forgings. The removal of the scale from sheet iron and steel prior to enamelling, galvanising, nickeling, tinning, &c.; the cleaning of tubes and brazed joints, largely used in bicycle work. Sharpening the teeth of files. For granulating or frosting electro-plate, gilding metal, gold and silversmiths' work, and jewellery; and the reduction to clean metal surfaces of larger works, ranging from the steel forgings of safes to armour plates.

On stone, slate and granite for incised carving and inscriptions in intaglio or relief; for cleaning off the grime from stone, granite and brick buildings, and, in contrast to this last, for the most delicate drawing for lithography.

Among other purposes it is employed for removing fur and deposits in tubes and tanks, for cleaning off accumulations of paint and dirt within iron ships, for roughening the surfaces of metal rollers, for decorating coat and other buttons, for granulating glass to give it a key for ornamental painting by hand, for piercing the apertures in glass ventilators, for marking cakes of cement and glue, for marking pottery and in the manufacture of ornamental tiles, for smooth facing bricks to receive white glass or enamel, for refacing grindstones, emery and corundum wheels; for granulating celluloid films for photography, and on wood to bring out the grain in relief, and latterly for blocks for printing.

A list of its users cannot be attempted, but includes the names of Sir W. Armstrong, Charles Cammel, Chatwood, Sir John Brown, Jessop, Sanderson, Turton, Vickers, many English and foreign railway companies, Arculus, Chance, Dixon, Hartley, Hole, Pilkington and others.

The protecting overlays used in glass decoration are made of a quick-drying, viscid mixture of glue, dextrine, glycerine and any powdered colouring matter to give body; they readily wash off in warm water after use. Sometimes they are painted on by hand; for many repetitions they are printed from wood-block patterns on paper, then laid on the glass, and the composition transferred by rubbing, or it is applied through thick tinfoil stencil plates with a palette knife. For figures and original designs the glass is entirely covered with a sheet of paper dipped in the mixture, through which, when dry, the design is cut out with a pointed knife. Sometimes numerous morsels of the prepared paper are separately attached to the glass.

In all stencil plates there are many isolated solid portions, as for example the centre of a letter o, which have to be retained in their positions by bars or ties, which cross and interfere with the continuity of the apertures desired around them. For the best works, required in quantities, this is overcome by using two or more tinfoil stencil plates, the first giving the design, and the second pierced only with holes corresponding to these ties to blot them out. On the table there are some such stencil plates, with impressions showing their separate and combined results, and glass with the completed overlay from them.

Large sheets of glazing glass covered with their overlays are frosted as to the ground or pattern, whilst gently travelling upon two long, wide, horizontal surfaces or tables placed end to end with a small interval between them, by means of a narrow, uniform stream of fine dry sand, extending the entire length of this interval, impelled upwards by exhaust air at about 1 lb. pressure, to strike the constantly moving glass. This very long, narrow jet issues from between two iron plates, a quarter of an inch distant at their upper edges, or mouth, but more separated and also open below, beneath which the sand, supplied from a long, horizontal, hollow-plate screw of 2-inch pitch, falls from a slit in its case to a trough, and is caught and carried up by the exhaust air. After striking the glass the sand falls back into a chamber separated from that below but connected with the exhaust, by which latter it is carried through large pipes to a drum or sand chamber above. In this, after

ALL MILLS, WAREHOUSES, THEATRES AND PUBLIC BUILDINGS CAN BE RENDERED ABSOLUTELY FIREPROOF BY ADOPTING THE
